**Abstract:** The cross-coupling reaction of (E)- and (Z)-1-alkenyldialkylboranes with (trimethylsilyl)ethynyl bromide proceeds in the presence of a base and a catalytic amount of Cu(acac)<sub>2</sub> under very mild conditions to provide conjugated enynes whose carbon-carbon triple bond is in distal position. The use of 1 M NaOMe as a base exclusively affords both (E)- and (Z)-3-alken-1-ynes with high regio- and stereoselectivity, while the use of LiOH·H<sub>2</sub>O instead of 1 M NaOMe preferentially gives both (E)- and (Z)-1-trimethylsilyl-3alken-1-ynes regio- and stereoselectively.

**Key words:** cross-coupling, 3-alken-1-yne, 1-trimethylsilyl-3-alken-1-yne, alkenyldialkylborane, (trimethylsilyl)ethynyl bromide

Conjugated envnes are valuable precursors to a variety of functionalized compounds such as polysubstituted benzenes via benzannulation reactions<sup>1</sup> and stereodefined conjugated dienes via semi-hydrogenation.<sup>2</sup> Furthermore, the enyne systems are found in a number of natural products such as laurencin<sup>3</sup> and neocarzinostatin chromophore.<sup>4</sup> Among conjugated envnes, there is a lively interest in 3-alken-1-yne due to its synthetic utility in which the acetylenic hydrogen can be converted into various functionalities including carbon-carbon bond formation. There have been several reports on the synthesis of 3-alken-1-yne using (trimethylsilyl)ethynyl halide as an ethynyl unit;<sup>5-7</sup> however, to the best of our knowledge, there are no reports of the combination of alkenylborane and (trimethylsilyl)ethynyl halide to afford 3-alken-1yne. The cross-coupling reaction using organoboranes, i.e. Suzuki-Miyaura-type reaction,<sup>8</sup> requires base together with catalyst, while sp-hybridized carbon-silicon bond can be readily cleaved by basic methanolysis. Thus it was of interest to examine whether the cross-coupling reaction of alkenylboranes with (trimethylsilyl)ethynyl halide in the presence of base could proceed in a selective fashion to give the sole product. In this communication, we report a general and accessible route to both (E)- and (Z)-3-alken-1-ynes (**2** and **5**) as well as an analogous route to both (E)- and (Z)-1-trimethylsilyl-3-alken-1-ynes (**3** and **6**) using the cross-coupling reaction of (E)- and (Z)-1-alkenyldialkylboranes (**1** and **4**) with (trimethylsilyl)ethynyl bromide.

We examined the reaction of (*E*)-1-octenyldialkylborane (1a) with (trimethylsilyl)ethynyl bromide, prepared by bromination of (trimethylsilyl)ethyne with NBS, under various conditions. It was found that the reaction using Cu(acac)<sub>2</sub> as catalyst proceeded under very mild conditions to yield two products, (E)-3-decen-1-yne (2a) and (E)-1-trimethylsilyl-3-decen-1-yne (3a) (Scheme 1). The reaction was carried out using several bases, and the results are shown in Table 1. The ratio of 2a to 3a was dependent on base employed. Thus, the reaction using 1 M NaOMe gave  $2a^9$  exclusively (entries 1, 8 and 9), while the reaction using LiOH·H<sub>2</sub>O gave 3a<sup>10</sup> preferentially (entries 6 and 7). In addition, the use of 1.5 equivalents amount of **1a** increased the yield of the products (entries 7 and 9). It was also observed that the ratio and the yield of the products were affected by changing the dialkylboryl group of 1a (entry 6 vs. 10 and entry 1 vs. 8).

Several types of (*E*)- and (*Z*)-1-alkenyldialkylboranes (1 and 4) were subjected to the reaction with (trimethylsilyl)ethynyl bromide under the conditions using two different bases, 1 M NaOMe and LiOH·H<sub>2</sub>O. The results summarized in Table 2 and Scheme 2 revealed that the exclusive formation of 2 and 5 as well as the highly selective

<sup>a</sup> Reactions were carried out at -15 °C to room temperature.

<sup>b</sup> GLC yields based on (trimethylsilyl)ethynyl bromide employed.

<sup>c</sup> 1.5 equivalents of (*E*)-1-octenyldialkylborane (1) was used.

formation of **3** and **6** was maintained completely or to a very similar extent in the cross-coupling reaction of 1 and 4 examined. The cross-coupling reaction of (Z)-1-octenyldialkylborane (4a), which was prepared by treatment of (Z)-1-iodo-1-octenyldialkylborane with LiBEt<sub>3</sub>H,<sup>11</sup> proceeded under similar conditions to lead the selective formation of (Z)-3-decen-1-yne  $(5a)^{12}$  (entry 2) and (Z)-1trimethylsilyl-3-decen-1-yne  $(6a)^{13}$  (entry 9) in the same manner as described in the reaction of 1a. It should be noted that the presence of such functional groups as alkenyl, chloro and alkoxy in R<sup>1</sup> did not affect the present reaction at all. For the synthesis of 5 it is important to remove  $Et_3B$ liberated from LiBEt<sub>3</sub>H (entries 2 and 7). In the presence of Et<sub>3</sub>B, for example, the cross-coupling reaction of 4a using 1 M NaOMe decreased the yield of **5a** substantially, probably due to consumption of NaOMe by forming NaBEt<sub>3</sub>OMe. In fact, further addition of NaOMe (2 equiv in total) restored the formation of **5a** to nearly the same yield. On the other hand, it is essential for the synthesis of **6a** to use DMF as co-solvent (entry 9). DMF appears to prevent interaction between **4a** and LiI generated in the step of the preparation of **4a**; indeed, the addition of LiI to **1a** decreased the yield of **3a** significantly. In the case where LiBr was generated, DMF was not required for the synthesis of (*Z*)-3-benzyloxy-1-trimethylsilyl-3-buten-1yne (**6e**, entry 14).

Although we have no clear evidence for the reaction mechanism at present, the intermediate of the present reaction might be copper(III) species, as previously reported by Liebeskind et al<sup>14</sup> and Evans et al,<sup>15</sup> rather than simple alkenyl copper. Concerning the formation of 3-alken-1yne, we believe that 1-trimethylsilyl-3-alken-1-yne would be formed at first even in the presence of 1 M NaOMe, and then the product would immediately undergo protodesilation with basic MeOH to produce 3-alken-1-yne.

The synthetic usefulness of 3-alken-1-yne thus prepared has been demonstrated by the palladium-copper catalyzed cross-coupling reaction with aryl halide (Sonogashira reaction).<sup>16</sup> For example, in the presence of aqueous tetrabutylammonium hydroxide<sup>17</sup> the reaction of **2a** and **5a** with iodobenzene using catalytic amounts of PdCl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub> and CuI proceeded smoothly at room temperature to provide (*E*)- and (*Z*)-1-phenyl-3-decen-1-yne,<sup>18</sup> respectively, in good overall yields in a one-pot manner from the preparation of bis(1,2-dimethylprop-yl)borane (Scheme 3).

In summary, we have developed a highly flexible protocol that allows the synthesis of (E)- and (Z)-3-alken-1-yne (**2** and **5**) with protodesilation as well as the synthesis of (E)- and (Z)-1-trimethylsilyl-3-alken-1-yne (**3** and **6**) without protodesilation. As shown in Scheme 3, successive coupling reaction of (E)- and (Z)-1-alkenyl group with two distinct electrophiles without isolation of any intermediates will provide a new synthetic route for linear conjugated compounds possessing an enyne unit. Further studies
