Studies on the Macrolides from Marine Dinoflagellate Amphidinium sp.: Structures of Amphidinolides R and S and a Succinate Feeding Experiment

Masami Ishibashi, Miho Takahashi, and Jun'ichi Kobayashi*

Faculty of Pharmaceutical Sciences, Hokkaido University, Sapporo 060, Japan

Abstract: Two new cytotoxic macrolides, amphidinolides R (1) and S (2), were isolated from the cultured marine dinoflagellate *Amphidinium* sp. and their structures including absolute configuration were elucidated on the basis of spectroscopic data as well as chemical experiments. In a feeding experiment of ^{13}C -labeled succinic acid into a culture of *Amphidinium* sp., no enrichment of the ^{13}C NMR signal intensity of any carbon of amphidinolide J (3), the most abundant macrolide in this dinoflagellate, was observed. © 1997 Elsevier Science Ltd.

During our continuing studies on bioactive substances from marine microalgae, we previously isolated a series of cytotoxic macrolides, named amphidinolides, possessing unique structural features from dinoflagellates of the genus *Amphidinium*.¹ We further investigated the constituents of this microalga (strain number, Y-5), which was a symbiont of Okinawan marine acoel flatworm of the genus *Amphiscolops*, and now isolated two new cytotoxic macrolides, amphidinolides R (1) and S (2). This paper deals with the isolation and structure elucidation of them possessing related structures to amphidinolide J (3), a 15-membered macrolide isolated from the same dinoflagellate.² Result of feeding experiments of ¹³C-labeled succinic acid into the culture of the dinoflagellate *Amphidinium* sp. was also described here.

The harvested algal cells (1205 g, wet weight, from 4956 L of culture) were extracted with MeOH/toluene (3:1) and partitioned between toluene and water. The toluene-soluble fraction was subjected to a silica gel column (CHCl₃/MeOH, 95:5), and the macrolide-containing fractions were subsequently separated by reversed phase chromatography on ODS (80% MeOH) and gel filtration on Sephadex LH-20 (CHCl₃/MeOH, 1:1). Further purifications by HPLC using reversed and normal phase columns yielded amphidinolides R (1, 0.0005%, wet weight) and S (2, 0.0001%) together with the known macrolide, amphidinolide J (3, 0.003%).

Amphidinolide R (1) was isolated as a colorless oil and its molecular formula was determined as C₂₄H₃₈O₄ by HRFABMS [*m*/z 391.2834 (M+H)⁺, Δ -1.4 mmu]. The IR spectrum suggested the presence of hydroxyl (3400 cm⁻¹) and ester (or lactone) (1720 cm⁻¹) groups, and its UV spectrum showed no characteristic absorptions. The ¹H and ¹³C NMR spectral data of 1 (Table 1) were revealed to be similar to those of amphidinolide J (3),² containing one ester carbonyl, one exomethylene, six sp² methine carbons, three oxymethines, three unoxygenated methines, five sp³ methylenes, and four methyl groups. The ¹H-¹H COSY spectrum of 1 showed correlations almost throughout the molecule (from H₂-2 to H₂-18 and from H₂-19 to H₃-20), and the connection between C-18 and C-19 was indicated from the HMBC cross-peak for H₃-20/C-18. From the ¹H-¹H COSY, HMQC, and HMBC spectral data of 1, the positions of secondary methyls, exomethylenes and other olefins, and oxymethines of 1 were deduced to be parallel to those of

amphidinolide J (3). Of the three oxymethine protons, the H-13 resonated particularly in the low-field ($\delta_{\rm H}$ 5.44), implying that the ester oxygen on C-1 was connected to C-13. Thus, the structure of amphidinolide R was elucidated as 1 having a 14-membered lactone moiety with different location of the lactone linkage from that of 3. Although attempts for acyl migration of 3 into 1 were unsuccessful by treatment with p-TsOH³ or

^{a)}*J*(H/H) in Hz. 1: 2a/2b=14.4, 2a/3=11.9, 2b/3=4.8, 3/21(3H)=7.0, 7/8=15.8, 8/9=6.6, 10/11=5.0, 10/23(3H)=6.9, 11/12=15.8, 12/13=7.5, 13/14=4.2, 14/15=4.2, 15/16=8.6, 15/24(3H)=6.9, 16/17=15.3, 17/18=6.8, and 19/20=7.4; 2: 2a/2b=16.0, 2a/3=11.1, 2b/3=3.4, 3/21(3H)=7.1, 6(2H)/7=6.9, 7/8=16.0, 10/11=8.6, 10/23(3H)=6.7, 11/12=15.7, 12/13=7.0, 13/14=1.3, 14/15=9.1, 15/16=8.9, 15/24(3H)=6.7, 16/17=15.3, 17/18=6.7, and 19/20=7.2; 3 (C₆C₆): 2a/2b=15.9, 2a/3=12.4, 2b/3=2.9, 3/21(3H)=6.8, 6a/7=10.3, 6b/7=4.4, 7/8=15.0, 8/9=8.8, 9/10=1.5, 10/11=9.2, 10/23(3H)=7.0, 11/12=15.8, 12/13=8.1, 13/14=1.8, 14/15=9.5, 15/16=8.1, 15/24(3H)=7.0, 16/17=15.4, 17/18=7.0, 18/19=7.3, and 19/20=7.3; 3 (DMF-d₁): 2a/2b=15.7, 2a/3=12.4, 2b/3=2.6, 3/21(3H)=6.8, 8/9=6.0, 9/10=1.8, 10/11=9.5, 10/23(3H)=7.2, 11/12=15.5, 12/13=8.2, 13/14=1.7, 14/15=10.0, 15/16=8.8, 15/24(3H)=6.6, 16/17=15.3, 17/18=6.8, 18/19=7.4, and 19/20=7.4.

b)Ratio of ¹³C NMR signal intensity of 3 fed with disodium [¹³C₂] succinate over natural abundance; ratio normalized to that of C-20 signal

Ti(O-*i*-Pr)4,⁴ treatment of each of 1 and 3 with sodium methoxide in methanol yielded an identical linear methyl ester (4, Scheme 1) on the basis of comparison of TLC, HPLC, and ¹H NMR as well as the sign of optical rotation. The evidence for the stereochemistry of six chiral centers (3*R*, 9*R*, 10*R*, 13*R*, 14*R*, 15*R*) in 1 was thus provided since the absolute stereochemistry of amphidinolide J (3) was already known.²

Amphidinolide S (2), also isolated as a colorless oil, had the molecular formula of C24H36O4 as established by HRFABMS [m/z 389.2686 (M+H)⁺, Δ -0.6 mmu], and showed a UV absorption (λ_{max} 224 nm) assignable to an α , β -unsaturated ketone. The ¹H and ¹³C NMR data (Table 1) indicated that amphidinolide S (2) was also structurally related to amphidinolide J (3), containing the corresponding functionalities such as one exomethylene, three disubstituted olefins, and four methyl groups. It was also suggested that amphidinolide S (2) possesses a ketone group and one less oxymethine carbon than 3. Interpretation of the $^{1}H^{-1}H$ COSY, HMQC, and HMBC spectral data of 2 revealed that the C-9 hydroxyl group in 3 was replaced by the ketone in 2 to form a conjugated enone, and structure of other part of molecule of 2 was parallel to that of amphidinolide J (3). This finding was further corroborated by the following experiments (Scheme 2). Treatment of amphidinolide J (3) with manganese dioxide in DMF at room temperature for 18 h afforded an oxidation product, which was identified to be amphidinolide S (2) by TLC, HPLC, and ¹H NMR analysis, and both were dextrorotatory. Thus, amphidinolide S (2) was revealed to be 9-dehydro derivative of amphidinolide J (3), possessing the same absolute configuration as amphidinolide R (1). Interestingly, when the MnO₂ oxidation was carried out in benzene solution, 13-keto derivative (5) was produced exclusively on the basis of HPLC analysis. The MnO2 oxidation in DMF did not afford 13-keto derivative (5), and no 9.13-diketo derivative was detected in the oxidation products in either DMF or benzene solution. The ¹H NMR of amphidinolide J (3) in DMF-d7 was recorded and was compared with that in C6D6 solution (Table 1). The proton-proton coupling constants in both solutions were almost comparative; however, a small difference was observed only between H-8 and H-9 (in DMF-d7: J8,9=6.0 Hz; in C6D6: $J_{8,9}=8.8$ Hz). Thus, a small difference in the conformation around the C-9 hydroxyl group of 3 in the two solvents might have resulted in the selective oxidation of C-9 or C-13 hydroxyl group depending on the solvent.

Amphidinolides R (1) and S (2) are two new cytotoxic 14- and 15-membered macrolides, respectively, possessing related structures to that of amphidinolide J (3).² Their structures including absolute

stereochemistry were established on the basis of chemical derivatization experiments. Compounds 1 and 2 showed cytotoxicity against murine lymphoma L1210 (IC50, 1.4 and 4.0 μ g/mL) and human epidermoid carcinoma KB cells (IC50, 0.67 and 6.5 μ g/mL) in vitro, respectively.

We previously reported a biosynthetic study of amphidinolide J (3) by feeding experiments with ^{13}C labeled sodium acetate precursors to show that all carbons in 3 were derived from acetates and the labeling pattern could not be accounted for by the classical polyketide pathway.⁵ We proposed that the unusual labeling patterns of 3 were derived from participation of dicarboxylic acids⁶; e.g., the C-1/C-2/C-3/C-21 unit labeled as "c-m-m-m"⁷ may come from α -ketoglutarate while the C-10/C-11/C-12 unit labeled as "c-m-m" may be derived from succinate.⁵ Wright and coworkers, however, recently described that the labeling pattern of 3 was explained by an oxidation and carbon deletion process in the polyketide chain which was proposed to proceed through flavin monooxygenase-mediated oxidation and a Favorski-type rearrangement.⁸ Hence we tried feeding experiment of ¹³C-labeled succinate into the dinoflagellate Amphidinium sp., especially amphidinolide J (3), the most predominant macrolide in this dinoflagellate. Disodium [1,2-13C2] succinate (6) was prepared from ethyl glyoxylate (7) and triethyl phosphonoacetate- ${}^{13}C_2$ as shown in Scheme 3. The 13 C-labeled succinate was fed to the alga (370 μ M) in one portion 10 days after inoculation, then 2 days later the culture was harvested. Amphidinolide J (3) was isolated from the extract of the harvested cells by improved procedures,⁵ and the ¹³C NMR of 3 obtained by this experiment showed no enhancement of the signal intensities of any carbons as shown in Table 1. Particularly, increase in signal intensities for the C-10/C-11/C-12 and C-1/C-2/C-3/C-21 unit as well as observation of satellites due to the ¹³C-¹³C coupling for these units had been expected, but no appreciable difference in the ^{13}C NMR spectrum was detected. Thus, incorporation of succinate into amphidinolide J (3) was not observed in this experiment. Evidence for accounting for the unusual labeling pattern of acetates therefore remains unprovided.

EXPERIMENTAL

General methods. Optical rotations were determined on a JASCO DIP-370 digital polarimeter and IR spectra were taken on a JASCO FT/IR-230 spectrometer. ¹H and ¹³C NMR spectra were recorded on Bruker ARX-500 and/or AMX-600 spectrometers. FAB mass spectra were obtained on a JEOL HX-110 spectrometer.

Isolation. The harvested cells of the cultured dinoflagellate *Amphidinium* sp. (1205 g, wet weight, from 4956 L of culture) were extracted with MeOH/toluene (3:1; 1 L x 3). After addition of 1 M NaCl (1.5 L), the mixture was extracted with toluene (500 mL x 4). The toluene-soluble fraction was evaporated under reduced pressure to give a residue (44 g), which was partially (26.7 g) subjected to a flash column

chromatography on silica gel (4.5 x 40 cm) eluted with CHCl3/MeOH (95:5). The fraction eluting from 330 to 615 mL (4.1 g) was then partially (1.0 g) separated by flash chromatography on ODS (YMC-GEL ODS 60 A, I-40/60, 20 x 70 mm; 80% MeOH), and subsequently separated by gel filtration on Sephadex LH-20 (4.0 x 100 cm; CHCl3/MeOH, 1:1) to give a macrolide-containing fraction (0.43 g). This fraction was further purified by reversed-phase chromatography (CPO-HS-221-20, Kusano Kagakukikai Co., 22 x 100 mm; flow rate, 2.5 mL/min; eluant, 60% CH3CN), followed by reversed-phase HPLC (Develosil ODS-5, Nomura Chemical, 10 x 250 mm; flow rate, 2.5 mL/min; detection, RI (refractive index) and UV at 220 nm; eluant, 73% CH3CN) to afford amphidinolide R (1, 1.1 mg, r_R 15.0 min) together with amphidinolide J (3, 6.8 mg, r_R 15.9 min). The fraction of this HPLC (1.7 mg, r_R 20.2 min) was subsequently separated by normal phase HPLC (YMC-Pack SIL-06, 4.6 x 250 mm; flow rate, 1.0 mL/min; eluant, hexane/2-propanol, 95:5) to give amphidinolide S (2, 0.2 mg, r_R 6.4 min).

Amphidinolide R (1): Colorless oil; $[\alpha]D^{20} + 23^{\circ}$ (c 0.53, MeOH); IR (film) v_{max} 3400 and 1720 cm⁻¹; ¹H and ¹³C NMR (Table 1); FABMS (positive, matrix: glycerol) *m/z* 391 (M+H)⁺; HRFABMS *m/z* 391.2834, Calcd for C₂₄H₃₉O₄: (M+H) 391.2848.

Amphidinolide S (2): Colorless oil; $[α]D^{20} + 5^{\circ}$ (c 0.17, MeOH); UV (MeOH) λ_{max} 224 nm (ε 6300); IR (film) ν_{max} 3450 and 1730 cm⁻¹; ¹H and ¹³C NMR (Table 1); FABMS (positive, matrix: glycerol) *m*/z 389 (M+H)⁺; HRFABMS *m*/z 389.2686, Calcd for C₂₄H₃₇O₄: (M+H) 389.2692.

Methyl Ester (4). A solution of amphidinolide J (3, 0.5 mg) in methanol (0.4 mL) was treated with a 28% sodium methoxide-methanol solution (20 µL) at room temperature for 15 h. After addition of water (1 mL), the mixture was extracted with EtOAc (1 mL x 4), and the EtOAc layer was dried over MgSO4 and evaporated under reduced pressure to give a residue, which was purified with HPLC (Develosil ODS-5, Nomura Chemical, 10 x 250 mm; flow rate, 2.5 mL/min; eluant, 70% CH₃CN) to afford the methyl ester (4, 0.3 mg, *t*_R 16.8 min): colorless oil; $[\alpha]D^{23}$ -75° (*c* 0.1, MeOH); IR (KBr) v_{max} 3440 and 1740 cm⁻¹; ¹H NMR (C6D6) δ 0.97 (3H, t, *J*=7.2 Hz), 1.01 (3H, d, *J*=7.1 Hz), 1.08 (3H, d, *J*=6.8 Hz), 1.17 (3H, d, *J*=7.0 Hz), 3.27 (1H, m), 3.39 (3H, s), 3.83 (1H, m), 4.07 (1H, m), 4.80 (1H, s), 4.84 (1H, s), 5.50 (2H, m), 5.59 (3H, m), and 5.83 (1H, dd, *J*=15.5 and 7.8 Hz); FABMS *m*/z 423 (M+H)⁺; HRFABMS *m*/z 423.3098, Calcd for C25H43O5: (M+H) 423.3110. Amphidinolide R (1, 0.5 mg) was also subjected to methanolysis by the same procedures as above to give the methyl ester (4, 0.4 mg), which was identified by comparison of ¹H NMR, TLC (silica gel; hexane/acetone, 3:1, Rf 0.31), HPLC (the same condition as above), and the sign of optical rotation.

MnO2 Oxidation of 3 in DMF. Amphidinolide J (3, 1.5 mg) dissolved in DMF (0.4 mL) was treated with MnO2 (100 mg) under argon atmosphere at rt for 18 h. After addition of ether (2 mL), insoluble material was removed by filtration, and the filtrate was concentrated *in vacuo* to give a residue, which was separated by HPLC (Develosil ODS-5, Nomura Chemical, 10 x 250 mm; flow rate, 2.5 mL/min; eluant, 73% CH₃CN) to afford amphidinolide S (2, 0.1 mg, t_R 20.2 min) together with starting amphidinolide J (3, 0.1 mg, t_R 15.9 min). Amphidinolide S (2) was identified by ¹H NMR, TLC (silica gel; hexane/acetone, 3:1, Rf 0.60), HPLC (the same condition as above), and the sign of optical rotation.

MnO2 Oxidation of 3 in Benzene. Amphidinolide J (3, 1.1 mg) dissolved in benzene (0.25 mL) was treated with MnO2 (100 mg) under argon atmosphere at rt for 18 h. After addition of ether (2 mL), insoluble material was removed by filtration, and the filtrate was concentrated *in vacuo* to give a residue, which was separated by HPLC (Develosil ODS-5, Nomura Chemical, 10 x 250 mm; flow rate, 2.5 mL/min; eluant,

73% CH₃CN) to give 13-dehydroamphidinolide J (5, 0.1 mg, tR 40.0 min) together with starting amphidinolide J (3, 0.1 mg, $t_{\rm R}$ 15.9 min). 13-Dehydroamphidinolide J (5): colorless oil; UV (MeOH) $\lambda_{\rm max}$ 239 nm (ϵ 8000); IR (film) v_{max} 3450, 1740, and 1690 cm⁻¹; ¹H NMR (C₆D₆) δ 7.29 (1H, m), 6.31 (1H, d, J=15.5 Hz), 5.55 (1H, dd, J=15.2 and 7.6 Hz), 5.48 (1H, d, J=15.2 and 6.4 Hz), 5.25 (1H, ddd, J=15.5, 9.3, and 1.3 Hz), 5.15 (1H, d, J=15.5, 7.5, and 5.6 Hz), 4.96 (1H, d, J=4.6 Hz), 4.87 (1H, s), 4.50 (1H, s), 3.78 (1H, m), 2.93 (1H, m), 1.17 (3H, d, J=6.9 Hz), 1.09 (3H, d, J=6.9 Hz), 0.87 (3H, d, J=6.7 Hz), and 0.86 (3H, d, J=7.3 Hz); FABMS (positive, matrix: glycerol) m/z 389 (M+H)+; HRFABMS m/z 389.2690, Calcd for C24H37O4: (M+H) 389.2692.

Preparation of Disodium [¹³C₂] Succinate (6). Ethyl glycolate (7, monomer) was prepared by distillation under reduced pressure (80 °C/153 mmHg) in the presence of 85% phosphoric acid (0.1% w/w) from its polymer form (Tokyo Kasei Kogyo Co. Ltd., G0264). A solution of triethyl phosphonoacetate- $^{13}C_2$ (99 atom % ¹³C, Aldrich 28384-3; 5 g) in THF (30 mL) was added to a suspension of potassium *tert*-butoxide (2.02 g) in THF (40 mL), and the mixture was stirred at room temperature for 40 min. The reaction mixture was cooled at - 60 °C, and the soultion of ethyl glycolate (7, monomer, 3.06 g) obtained as above in THF (30 mL) was added. The mixture was stirred for 2 h at - 40 °C and then 30 min at - 20 °C. After addition of brine (50 mL), the mixture was extracted with EtOAc (50 mL x 3), dried over MgSO4, and evaporated under reduced pressure to give a residue, which was purified with silica gel column chromatography (hexane/EtOAx, 40:1) to give a 1:1 mixture of $[1,2-1^{3}C_{2}]$ diethyl maleate and $[1,2-1^{3}C_{2}]$ diethyl fumarate (2.50 g, 64% yield based on ¹³C-labeled reagent). The 1:1 E/Z mixture (2.50 g) in ethanol (50 mL) was treated under hydrogen atmosphere in the presence of 5% Pd-C (210 mg) at room temperature for 6 h. After filtration of the catalyst through celite, the filtrate was evaporated under reduced pressure to give $[1,2-1^{3}C_{2}]$ diethyl succinate, which was hydrolyzed by treatment with conc. hydrochloric acid (5 mL) at 40 °C for 4 h. Evaporation of the mixture in vacuo afforded [1,2-13C2] succinic acid, which was neutralized with 3 M NaOH aqueous solution, and the solution was lyophilized to give disodium [1,2-¹³C₂] succinate (1.87 g, 79% in 3 steps).

Incubation with Disodium [¹³C₂] Succinate (6). Culturing was carried out by essentially the same conditions as those described previously.⁹ On day 10 after inoculation, the labeled succinate (370 µM) was added, and the culture was harvested on day 12. The harvested algal cells (28.4 g, wet weight, from 80 L of culture) was extracted and purified by the procedures described previously⁵ to give amphidinolide J (3, 0.6 mg).

Acknowledgment: We are grateful to Prof. T. Sasaki, Kanazawa University, for cytotoxic tests. This work was partly supported by a Grant-in-Aid from The Naito Foundation and a Grant-in-Aid for Scientific Research from the Ministry of Education, Science, Sports, and Culture of Japan.
