Supporting Information

ABSTRACT: Heat shock protein 90 (Hsp90) facilitates the maturation of many newly synthesized and unfolded proteins (clients) via the Hsp90 chaperone cycle, in which Hsp90 forms a heteroprotein complex and relies upon cochaperones, immunophilins, etc., for assistance in client folding. Hsp90 inhibition has emerged as a strategy for anticancer therapies due to the involvement of clients in many oncogenic pathways. Inhibition of chaperone function results in client ubiquitiny-lation and degradation via the proteasome, ultimately leading

to tumor digression. Small molecule inhibitors perturb ATPase activity at the N-terminus and include derivatives of the natural product geldanamycin. However, N-terminal inhibition also leads to induction of the pro-survival heat shock response (HSR), in which displacement of the Hsp90-bound transcription factor, heat shock factor-1, translocates to the nucleus and induces transcription of heat shock proteins, including Hsp90. An alternative strategy for Hsp90 inhibition is disruption of the Hsp90 heteroprotein complex is an effective strategy to prevent client maturation without induction of the HSR. Cucurbitacin D, isolated from *Cucurbita texana*, and 3-epi-isocucurbitacin D prevented client maturation without induction of the HSR. Cucurbitacin D also disrupted interactions between Hsp90 and two cochaperones, Cdc37 and p23.

T sp90 is a molecular chaperone responsible for the correct Conformation of many newly synthesized polypeptides and the rematuration of denatured proteins termed "clients" via the Hsp90 chaperone cycle. Hsp90 functions as a homodimer and requires the formation of the heteroprotein complex composed of several immunophilins, cochaperones, and partner proteins for assistance in chaperone activity. Several conformational transitions of the Hsp90 heteroprotein-client complex, coupled to Hsp90 ATPase activit,y results in correct folding and release of client protein.^{1,2} Inhibition of the chaperone cycle leads to client protein ubiquiltinylation and subsequent degradation via the proteasome. $^{3-5}$ Hsp90 inhibition has emerged as a strategy for anticancer chemotherapeutics due to the involvement of Hsp90-dependent clients in a variety of oncogenic signaling pathways.^{6–11} Many clients (i.e., ErbB2, B-Raf, Akt, steroid hormone receptors, mutant p53, HIF-1, survivin, telomerase, etc.) are contributors to the six hallmarks of cancer. Oncogenic client degradation via Hsp90 inhibition ultimately halts cancer progression and has been observed during clinical trials of Hsp90 inhibitors.

Classic small molecule Hsp90 inhibitors are designed to perturb N-terminal ATPase activity and include derivatives of geldanamycin (1) (Figure 1), radicicol, and several purine analogs.¹² Although Hsp90 N-terminal inhibitors are effective at inhibiting Hsp90 function and lead to tumor digression through client degradation, N-terminal inhibition also leads to displacement of the Hsp90-bound transcription factor, heat shock factor-1 (HSF-1), and induction of the pro-survival heat

Figure 1. Structures of geldanamycin (GDA) (1), celastrol (2), and gedunin (3).

shock response (HSR).^{13–16} Upon displacement, HSF-1 trimerizes, translocates to the nucleus, and induces transcription of the heat shock element. This leads to increases in the cellular concentration of heat shock proteins, including Hsp90, and resulted in dosing and scheduling problems during clinical trials of N-terminal inhibitors. Therefore, anticancer Hsp90 inhibitors that avoid induction of the HSR are needed.

Alternative strategies to inhibit the chaperone cycle include targeting the Hsp90 C-terminus and disruption of the heteroprotein complex. C-Terminal inhibitors include derivatives of the coumarin-containing natural product novobiocin. $^{17-20}$ These inhibitors prevent cancer cell proliferation at

concentrations similar to N-terminal inhibitors and destabilize Hsp90-client protein interactions without induction of the HSR. Maturation of all clients requires additional proteins that interact with Hsp90 and modulate ATPase activity and/or assist in correct client folding.^{21,22} For example, the cochaperone Hsp90-Hsp70 organizing protein (HOP) associates with the Hsp90 dimer during the initial stages of the chaperone cycle and facilitates the delivery of certain clients from Hsp70 to Hsp90. Peptidyl-prolyl isomerase cochaperones (PPIases) assist in the correct folding and 3-diminsional structure of clients, and the cochaperone p23 promotes the optimal Hsp90 conformation for ATP binding and hydrolysis, ultimately resulting in client protein release.²³ In addition, classes of clients require the assistance of specific cochaperones for maturation (e.g. all Hsp90-dependent kinases require the assistance of the cochaperone cell division cycle 37 (Cdc37) for maturation). Disruption of interactions between Hsp90 and client-specific cochaperones may allow for select degradation of clients and avoid systemic client protein degradation, a consequence of Hsp90 inhibitors under current clinical investigation, and may be the cause of certain side effects.

The cucurbitacin class of natural products is a group of triterpenoids that are present in the Cucurbitaceae and other closely related families. More than 50 cucurbitacins have been identified and exhibit a wide variety of biological activities that include, but are not limited to, cytotoxicity, antiproliferation, anti-inflammation, antioxidant, antihepatotoxicity, antibacterial, and antiviral properties, as well as antimetastatic properties and improved anticancer activity when combined with current chemotherapies.^{24–26} Despite the presence of an α -, β unsaturated ketone (Michael acceptor; a well-established and nonspecific disruptor of general cellular processes via electrophilic chemical reactivity) located within many of the cucurbitacin compounds, several cucurbitacins interact with specific cellular targets involved in gene regulation, transcription, and overall cellular fate. Cucurbitacin D (4) reduced the proliferation of T-cell leukemia cells and ultimately led to cancer cell apoptosis.²⁷ This cucurbitacin was shown to affect the NF-*k*B pathway and led to the accumulation of NF-*k*B and I κ B- α within the cytosol. Interestingly, a decrease in the cellular levels of Bcl-xL and Bcl-2 was also observed. Bcl-xL and Bcl-2 levels are regulated by Hsp90 clients that depend on the chaperone cycle for correct folding and function. It has been reported that incubation with N-terminal inhibitors led to cellular decreases in Bcl-xL and Bcl-2 levels.^{28,29} Furthermore, 4, as well as other cucurbitacins, share structural similarities to the natural products celastrol (2) and gedunin (3), which are known inhibitors of client maturation via disruption of the Hsp90 heteroprotein complex (Figure 1). However, these natural products inhibit chaperone function by different mechanisms. 2 covalently binds the Hsp90 N-terminus and disrupts the interaction between Hsp90 and Cdc37, ultimately resulting in kinase client degradation.³⁰ 3 binds the cochapreone p23 and disrupts Hsp90-cochaperone interactions, leading to client degradation across many different cancer cell lines.³¹ Given certain structural similarities between the cucurbitacins, 2 and 3, as well as decreased levels of proteins that depend on functional clients after exposure to cucurbitacins, it was hypothesized that 4, and other cucurbitains, may inhibit the Hsp90 chaperone cycle in a manner similar to 2 and/or 3.

Herein, we report that 4 prevented the maturation of Hsp90dependent clients by disruption of the Hsp90 heteroprotein complex. With the exception of 23,24-dihydrocucurbitacin D (9) and 23,24-dihydrocucurbitacin B (10), all cucurbitacins exhibited antiproliferative IC₅₀ values at nanomolar concentrations against the MCF7 breast cancer cell line. Western blot analysis for client levels in the presence of high and low concentrations of each cucurbitacin revealed that incubation with 4 and 3-epi-isocucurbitacin D(6) led to client degradation. 4 also disrupted the interaction between Hsp90 and the cochaperones Cdc37 and p23; however, 6 did not disrupt these Hsp90-co-chaperone interactions components and caused client degradation through alternative mechanism(s). Furthermore, 4 did not induce the HSR, as no increases in the levels of heat shock proteins Hsp90, Hsp70, or Hsp27 was observed. Client protein degradation, disruption of Hsp90-Cdc37 and Hsp90p23 interactions as well as a lack of heat shock protein induction, notably Hsp27, has previously been observed after incubation with 3 and suggested 4 inhibited cancer cell growth through Hsp90 client degradation via disruption of Hsp90-cochaperone interactions by a mechanism comparable to 3.

RESULTS AND DISCUSSION

Cucurbitacin D (4) and cucurbitacin B (5), along with isomeric 3-*epi*-isocucurbitacin D (6), were isolated from the fruits of *Cucurbita texana* (Cucurbitaceae) following previously described protocols (Figure 2).³²⁻³⁴ Two additional oxidized

Figure 2. Chemical structures of cucurbitacins isolated from *Cucurbita texana* (Cucurbitaceae) [cucurbitacin D (4) and B (5); 3-epiisocucurbitacin D (6); cucurbitacin I (7) and E (8)] and the structures of the semisynthesized natural products [3-epi-cucurbitacin D (6), cucurbitacin I (7), 23,24-dihydrocucurbitacin D (9) (cucurbitacin R) and B (10)].

derivatives, cucurbitacin I (7) and E (8), were obtained as well. These latter compounds along with 6 were obtained in reduced quantities compared to that of 4 and 5. Fortunately, semisynthetic approaches to these particular compounds have been investigated in the literature and can be seen as a solution to the lack of material for these natural products. In addition, 9, 10, and other reduced C23–24 derivatives have routinely been acquired via hydrogenation conditions. Structures of the isolated and semisynthesized cucurbitacins of interest are shown in Figure 2.

The isomerization of the α -hydroxyketone at C2 and C3 of some cucurbitacins has been determined to take place under both acidic and basic conditions, with the most thorough investigation having been performed by Galindo and coworkers.^{35,36} However, an alternative to Galindo's procedure was chosen instead, one similar to that reported by Sneden et al. that takes advantage of the slightly acidic nature of silica gel.³⁷ Heating a CH_2Cl_2 solution of 4 and silica gel to 40 °C provided useful quantities of 6 for biological evaluation and the ability to recover unreacted 4 (Scheme 1).

Scheme 1. Semisynthesis of Cucurbitacins: 3-epi-Isocucurbitacin D (6), Cucurbitacin I (7), 23,24-Dihydrocucurbitacin D (9) (Cucurbitacin R), and 23,24-Dihydrocucurbitacin B $(10)^a$

^aReagents and conditions: (a) silica gel, CH_2Cl_2 , 40 °C, 25% (30% conversion); (b) Pd(OAc)₂, PhBr, NaOAc, DMA, 80 °C, 38% (60% conversion); (c) H_2 (1 atm), Pd/C 5%, EtOH, 88%.

While attempting to form cucurbitacin derivatives via a Heck reaction,³⁸ in an effort to improve their biological activity, an undesired product was isolated and later determined by spectroscopic analysis to be 7. Even though this is not the first report of the oxidation of the α -hydroxyketone to a diosphenol moiety for cucurbitacins,^{39–41} this is the first example of the transformation via a Saegusa oxidation (Scheme 1).^{42–45} This result can be rationalized via the ability of cucurbitacins to isomerize to form the intermediate enediol, which can be trapped and oxidized to the final diosphenol product. This is the same enediol intermediate that is necessary for the formation of isocucurbitacins. While 7 was not the initially desired product, the resulting extra quantity was now available for biological testing.

To date, *Cucurbita texana* has not produced any 9 or 10 via natural product isolation. However, hydrogenation of the C23–24 olefin of 4 and 5 has allowed for the ability to obtain useful quantities of the semisynthesized 9 and 10 from a plant species that does not routinely provide them through natural product isolation (Scheme 1).^{35,40,46–52}

Select Cucurbitacins Exhibit Potent Antiproliferative Activity and Decreased Hsp90-Dependent Client Protein Levels without Induction of the HSR. Consistent with previous data against several cancer cell lines, many of these cucurbitacins exhibited nanomolar IC_{50} values against the MCF7 breast cancer cell line. The decrease in potency observed for 9 and 10 may be explained by reduction of the α -, β unsaturated ketone. This would reduce the potential for nonspecific, attack by cellular nucleophiles. The IC_{50} values for each cucurbitacin can be found in Table 1 along with values for 1, an Hsp90 N-terminal inhibitor, 2, and 3.

Hsp90 inhibitors and disruptors of the heteroprotein complex prevent cancer cell proliferation at concentrations near the IC₅₀ value by depleting levels of clients necessary for cancer cell growth. To correlate client degradation via inhibition of the chaperone cycle to the IC₅₀ value for each cucurbitacin, client levels from MCF7 cell lysates dosed with high and low concentrations (5 times the IC_{50} value and half of the IC_{50} value, respectively) of each cucurbitacin were dectected by Western blot analysis. The levels of heat shock proteins were also detected to account for induction of the HSR as well as the levels of p23 and Cdc37. Incubation with high concentrations of the control compounds 1, 2, and 3 led to client protein degradation and little change in the levels of Cdc37 and p23 (Figure 3A). Consistent with previous reports, incubation with GDA led to increased levels of Hsp90, Hsp70, and Hsp27, indicating induction of the HSR (Figure 3A). Minimal induction of the HSR was observed at the concentrations of 2 and 3 tested; incubation with 3 caused only a slight increase in Hsp70 levels, and the levels of Hsp90 and Hsp27 were comparable to vehicle control upon incubation with 2 and 3 (Figure 3A).

Levels of clients and heat shock proteins after incubation with high and low concentrations of each cucurbitacin can be found in Figure 3B and within the Supporting Information (Figures S1 and S2). Incubation with high concentrations of 4 and 6 led to a decrease in client levels (Supporting Information, Figure S3), indicating disruption of client maturation. These cucurbitacins also decreased client levels in a dose-dependent manner at and around their IC₅₀ values (Figure 3B). No changes in Hsp90 or Hsp70 levels were observed; however, Hsp27 levels were increased at high concentrations of 6. The levels of Cdc37 and p23 remained constant at all concentrations (Supporting Information, Figure S3, and Figure 3B). Client and heat shock protein levels were unchanged after incubation with high and low concentrations of the remaining cucurbitacins (Supporting Information, Figure S1 and S2). No client degradation at high concentrations of compound and constant heat shock protein levels at high and low concentrations indicates the mechanism(s) by which these compounds inhibited MCF7 cancer cell growth is unrelated to Hsp90 inhibition.

Cucurbitacin D, But Not 3-epi-Isocucurbitacin D, Caused Client Protein Degradation through Disruption

Article

Figure 3. (A) Western blot for the levels of Hsp90 clients (pAkt, Her2, Cdk6, and Raf), heat shock proteins (Hsp90, Hsp70, and Hsp27), cochaperones (Cdc37 and p23), and actin from MCF7 cell lysates treated for 24 h with vehicle (0.25% DMSO) or high concentrations (5 times the IC_{50} value) of the controls geldanamycin (GDA) (1), celastrol (2), gedunin (3). (B) Levels of Hsp90 clients, heat shock proteins and cochaperones from cell lysates treated with vehicle or increasing concentrations of cucurbitacin D (4) or 3-epi-isocucurbitacin D (6).

of Hsp90-cochaperone Interactions. Concentration-dependent client degradation void of induction of the HSR indicates an alternative mechanism to traditional N-terminal inhibitors for preventing client maturation. Compounds such as 2 and 3 disrupt the Hsp90 heteroprotein complex, thereby preventing cochaperone assistance during the chaperone cycle. In addition, concentrations of these compounds that destabilize the heteroprotein-client complex do not induce the HSR. There are several reports of 2 and 3 as Hsp90 modulators present in literature. These natural products disrupt the interactions between Hsp90 and cochaperones involved in both early and late stages of the chaperone cycle. Celastrol (2) was shown to covalently bind the Hsp90 N-terminus, thereby disrupting Hsp90 from interacting with Cdc37, a cochaperone involved during the early stages of the chaperone cycle.53 Gedunin (3) binds the cochaperone p23 and prevents p23 from facilitating progression of the Hsp90 chaperone cycle.³¹ This ultimately results in improper trafficking and localization of clients, such as the steroid receptor, glucocorticoid receptor.

Consistent with previous studies, Figure 4A confirmed that high concentrations of 2 and 3 disrupted components of the

heteroprotein complex, while the N-terminal inhibitor 1 did not disrupt these Hsp90-*co*-chaperone interactions. Co-immunoprecipitation of Cdc37 and p23 was disrupted in the presence of high concentrations of 2 and 3 when using an antibody targeting Hsp90. A high concentration of 4 also disrupted these heteroprotein complex components from Hsp90 (Figure 4B). Incubation with a high concentration of 4 completely disrupted Hsp90–Cdc37 and Hsp90–p23 interactions from MCF7 cell lysates. Interestingly, a high concentration of 6 had no effect on the interactions between Hsp90 and these cochaperones; Hsp90–Cdc37 and Hsp90–p23 interactions remained intact at high and low concentrations of 6 (Figure 4B).

These data suggested that, although 4 and 6 both resulted in client protein degradation, the mechanisms by which these compounds disrupted client maturation are different. 4 disrupted Hsp90–Cdc37 and Hsp90–p23 complexes, which ultimately led to a cellular decrease of client levels. 6 also reduced client levels but did not affect these Hsp90-cochaperone interactions. This cucurbitacin may directly inhibit Hsp90 and bind an alternative site to the N-terminal ATP-binding pocket (e.g., C-terminal inhibitors, sansalvamide A,

Figure 4. (A) Co-immunoprecipitation of Cdc37 and p23 using an anti-Hsp90 antibody (abcam) from MCF7 cell lysates treated for 24 h with vehicle (0.25% DMSO) or high concentrations (5 times the IC₅₀ value) of the controls geldanamycin (GDA; final concentration = 0.2135 μ M) (1), celastrol (final concentration = 0.765 μ M) (2), gedunin (final concentration = 54.5 μ M) (3). (B) Co-immunoprecipitation of Cdc37 and p23 using an anti-Hsp90 antibody from cell lysates treated with high and low concentrations (5 times the IC₅₀ value and half the IC₅₀ value, respectively) of cucurbitacin D (final [H] concentration = 0.765 μ M; final [L] concentration = 0.299 μ M) (4) or 3-*epi*-isocucurbitacin D (final [H] concentration = 3.590 μ M; final [L] concentration = 3.590 μ M; final [L] concentration = 0.359 μ M) (6).

etc.), bind and inhibit the function of proteins important for client maturation (e.g., efrapeptins, cruentaren A, etc.), or disrupt interactions of other protein with the Hsp90 heteroprotein complex.⁵⁴⁻⁵⁶

High Concentrations of Cucurbitacin D Did Not Increase Cellular Levels of Hsp27. Patwardhan et al. reported that 3 does not induce the HSR in several different cancer cell lines, including the cervical cancer cell line HeLa and the breast cancer cell lines Hs578T and MCF7.³¹ More specifically, no increases in the levels of Hsp90, Hsp70, or Hsp27 were observed after incubation with concentrations up to 160 μ M of 3. To corroborate Western blot and coimmunoprecipitation data reported here and further verify 4 disrupted client protein maturation in a manner comparable to 3, Hsp27 levels were detected after incubation with high concentrations of 3, 4, and 6. MCF7 cells incubated with 5 and 10 times the IC₅₀ value of each compound, and levels of Hsp27 were detected via Western blot analysis (Figure 5). The levels of Hsp27 were unchanged after incubation with high concentrations of 3 and 4 and comparable to vehicle control; however, increased Hsp27 levels were observed at high concentrations of 6 and are consistent with Figure 3B.

Collectively, these data suggest that 4 destabilized client maturation through similar mechanisms to 3 by disruption of Cdc37 and p23 from the Hsp90 heteroprotein complex; however, 4 exhibited a dramatic 18-fold increase in potency when compared to 3. 6 also led to client degradation at nanomolar concentrations, but did not disrupt Hsp90–Cdc37 or Hsp90–p23 interactions and is presumed to cause degradation by alternative mechanisms. Like 3, no increase in Hsp27 levels was observed at high concentrations of 4, yet Article

Figure 5. Western blot for Hsp27 and actin levels from MCF7 cell lysates treated for 24 h with vehicle (0.25% DMSO), 5 times (5×) ,or 10 times (10×) the IC₅₀ value of the gedunin (final 5× concentration = 54.5 μ M; final 10× concentration = 109.0 μ M) (3), cucurbitacin D (final 5× concentration = 0.765 μ M; final 10× concentration = 5.980 μ M) (4) and 3-*epi*-isocucurbitacin D (final 5× concentration = 3.590 μ M; final 10× concentration = 7.180 μ M) (6).

increased levels of Hsp27 were detected at high concentrations of **6**, further supporting alternative mechanisms of client degradation for these cucurbitacins. In conclusion, the curcurbitacins have been shown to affect multiple cellular pathways and exhibit potent inhibitory activity against many cancer cell lines. Here we report the antiproliferative activity of cucurbitacin D and 3-*epi*-isocucurbitacin D is partly attributed to disruption of Hsp90 client protein maturation and cucurbitacin D destabilizes components of the Hsp90 heteroprotein complex, ultimately resulting in client degradation.

EXPERIMENTAL SECTION

General Experimental Procedures. Experimental data for each isolated compound was compared to previously reported literature data. NMR spectra were acquired on a Bruker AVANCE-400 MHz NMR spectrometer and compared to previously published data. Highresolution mass spectrometry (HRMS) data was obtained using either electron ionization (EI) on a ThermoFinnigan MAT 95 XL mass spectrometer or electrospray ionization (ESI) on a ThermoFinnigan LCQ Advantage ion trap liquid chromatography-mass spectrometer (LC/MS). Melting points were determined on a Vernier Melt Station melting point apparatus. TLC analysis was performed using precoated silica gel PE sheets (UV₂₅₄, 250 μ m layer). Compounds were purified via column chromatography using silica gel 40–63 μ m (230–400 mesh), preparative normal phase-TLC (silica gel, UV₂₅₄, 2 μ m layer), and reverse phase HPLC using a Dynamax liquid chromatograph (Varian Chromatography Systems) with a PDA-2 photodiode array UV detector (Alltech preparative column, Econosil C18 10 μ m, length 250 mm, ID 22 mm). Gradients of MeOH/H2O or ACN/H2O were utilized with a 9 or 13 mL/min flow rate. Analytical separations were optimized on an Alltima C18 (Alltech analytical column, 5 μ m, length 250 mm, ID 4.6 mm) HPLC column using a flow rate of 1 mL/min then transferred to preparative scale. All reagents and solvents were obtained from commercial suppliers and used as received.

Isolation and Semisynthesis of Cucurbitacins. Fruits from *Cucurbita texana* (Cucurbitaceae) were cut into pieces and homogenized with MeOH and filtered, and the solvent was removed under reduced pressure. The residue was subjected to flash column chromatography with gradient elution (hexane/EtOAc and then EtOAc/MeOH of increasing polarity). The fractions containing the same compounds as determined by TLC, were combined, and subjected to further purification by one of three methods: normal phase column chromatography, preparative normal phase TLC, or preparative reverse phase HPLC.^{32–35} The spectroscopic data for the pure isolated compounds were compared to published literature data: (1) cucurbitacin D (4);^{57–59} (2) cucurbitacin B (5);^{52,60} (3) 3-epiisocucurbitacin D (6);^{57,61,62} (4) cucurbitacin I (7);^{60,63} (5) cucurbitacin E (8);^{60,63} (6) 23,24-dihydrocucurbitacin D (9);⁶⁴ (7) 23,24-dihydrocucurbitacin B (10);^{52,65} (8) data for multiple cucurbitacins.

Preparation of 3-epi-lsocucurbitacin D (6). Cucurbitacin D (4) (50 mg, mmol) was added to a suspension of silica gel (3 g) in CH_2Cl_2 (5 mL). The reaction was heated to 40 °C for 72 h. The solution was allowed to cool, followed by dilution with EtOAc and filtration through plug of silica gel. The crude mixture was purified via preparative normal phase TLC to provide 3-epi-isocucurbitacin D (6) (13 mg) as a white solid in 25% yield.

Preparation of Cucurbitacin I (8). Palladium acetate (5 mg, 0.022 mmol, 0.3 equiv) was added to a vial containing cucurbitacin D (4) (44 mg, 0.085 mmol, 1 equiv), NaOAc (4 mg, 0.043 mmol, 0.5 equiv), and bromobenzene (0.01 mL, 0.095 mmol, 1.1 equiv) dissolved in dimethylacetamide (DMA) (0.40 mL). The vial was sealed with a Teflon lined cap, and the reaction was stirred at 80 °C for 24 h. The reaction was allowed to cool and diluted with EtOAc (10 mL) and H₂O (5 mL), followed by extracting the aqueous layer three times with EtOAc. The combined organic layers were washed with brine and dried over anhydrous Na₂SO₄. The crude product was initially purified via column chromatography using hexane/EtOAc to remove residual DMA. Minor impurities were further removed via preparative reverse phase HPLC using MeOH/H₂O, resulting in the isolation of cucurbitacin I (8) (16 mg) as a white solid in 38% yield (unoptimized reaction conditions).

Preparation of 23,24-Dihydrocucurbitacin D (10) (Cucurbitacin R) and 23,24-Dihydrocucurbitacin B (11). First, 5% palladium on carbon (16 mg) was added to a 25 mL round-bottom flask containing the desired cucurbitacin starting material (44.0 mg) dissolved in EtOH (5 mL). Then a septum was added to the flask, the headspace was flushed with H_{22} and the reaction was stirred for 4 h at 1 atm H_{22} . Upon completion, the reaction was filtered through a plug of silica gel using EtOAC. The crude product was purified using column chromatography (hexanes/EtOAc) to provide the desired dihydro compounds as white solids in 76–88% yield.

Antibodies and Reagents. Antibodies targeting Her2, Cdk6, phospho-Akt (pAkt), and Hsp27 were purchased from Cell Signaling Technology. Antibodies targeting Raf and actin were purchased from Santa Cruz Biotechnology. The remaining antibodies are listed and were purchased from the indicated vendors: Hsp90 (Enzo Life Sciences), Hsp70 (Assay Designs), and Cdc37 and p23 (Abcam). Gedunin was isolated in house. Celastrol was purchased from Cayman Chemical, and geldanamycin was purchased from Sigma-Aldrich.

Cell Culture. MCF7 cells were maintained in Advanced DMEM/ F12 (1:1; Gibco) supplemented with streptomycin (500 μ g/mL; Corning Cellgro), penicillin (100 units/mL; Corning Cellgro), Lglutamine (2 mM; Corning), and 10% FBS (Atlanta Biologicals). Cells were grown in a humidified atmosphere (37 °C, 5% CO₂) and passaged when confluent.

Antiproliferation. Cells were grown to confluence, seeded (2000 cells/well, 100 μ L total media) in clear, flat-bottom 96-well plates and allowed to attach overnight. Varying concentrations of compound in DMSO (1% DMSO final concentration; Sigma-Aldrich) was added. Cells were returned to the incubator for an additional 72 h. After 72 h, cell growth was determined using an MTS/PMS cell proliferation kit (Promega) per the manufacturer's instructions. Cells that incubated in 1% DMSO were used as 100% proliferation (i.e., DMSO = 100% growth), and the relative growth for each compound concentration was compared to 1% DMSO. IC₅₀ values were calculated from two separate experiments performed in triplicate using GraphPad Prism 6.0 (GraphPad Software).

Western Blot. MCF7 cells were grown to confluence and seeded at 0.4×10^6 cells/well/2 mL. Cells were incubated for 24 h and treated with varying concentrations of compound in DMSO (0.25% DMSO final concentration) or vehicle (DMSO) for 24 h. Cells were harvested in cold DPBS (Corning Cellgro) and lysed using MPER (Thermo Scientific) supplemented with protease and phosphatase inhibitors (Roche) according to the manufacturer's directions. Lysates were clarified at 14000g for 10 min at 4 °C. Protein concentrations were determined using the Pierce BCA protein assay kit per the manufacturer's instructions. Equal amounts of protein (20 μ g) were suspended in Laemmli sample buffer (15 μ L; BioRad) and boiled at 70 °C for 15 min. Samples were then electrophoresed under reducing

conditions (10% and 12% acrylamide gels; made in house), transferred to PVDF (0.45 μ m; Thermo Scientific), and immunoblotted with the corresponding antibody. Membranes were incubated with an appropriate horseradish peroxidase-labeled secondary antibody (Santa Cruz Biotechnology and GE Healthcare), developed with a chemiluminescent substrate, and visualized.

Co-immunoprecipitation. MCF7 cells were grown to confluence and seeded at 2 \times 106 cells/5 mL in 10 cm dishes. Cells were incubated for 24 h and then treated with compound in DMSO (0.25% DMSO final concentration) or vehicle (DMSO) for 24 h. Media and cells were collected with DPBS and centrifuged at 200g for 5 min at 4 °C. Supernatant was aspirated, and pellets were washed one time with cold DPBS and centrifuged. Supernatant was aspirated, and cell pellets were subsequently suspended in nondenaturing lysis buffer (20 mM Tris-HCl at pH 7.5, Fisher Scientific; 25 mM KCl, Sigma-Aldrich; 2 mM MgCl, Fisher Scientific; 2 mM DTT, Sigma-Aldrich; 20 mM sodium molybdate, Sigma-Aldrich; 2 mM ATP, Sigma-Aldrich; and 0.1% NP-40, US Biological) supplemented with protease and phosphatase inhibitors (Roche) and incubated on ice for 2 h. Lysates were clarified at 14000g for 10 min at 4 °C. Protein concentrations were determined using the Pierce BCA protein assay kit per the manufacturer's instructions. Equal protein (400 μ g) was incubated with 1 μ g of Hsp90 antibody (H90.10; abcam) in 500 μ L total volume of lysis buffer for approximately 2 h with rocking at 4 °C. Following incubation, 30 μ L of resuspended MagBeads Protein G (GenScript) were added to each sample and incubated with rocking for 1.5 h at 4 °C. Protein G beads were washed 3 times with lysis buffer (500 μ L), suspended in Laemmli sample buffer (15 μ L), and boiled at 70 °C for 15 min to dissociate proteins from beads. Samples were electrophoresed under reducing conditions (12% acrylamide gels; made in house), transferred to PVDF, and immunoblotted with the indicated antibodies. Membranes were incubated with a species-appropriate horseradish peroxidase-labeled secondary antibody, developed with a chemiluminescent substrate, and visualized.

ASSOCIATED CONTENT

Supporting Information

Western blot for Hsp90 client proteins (pAkt, Her2, and Cdk6) and heat shock proteins (Hsp70 and Hsp90) from cell lysates dosed for 24 hours with high and low concentrations of each cucurbitacin; ¹H NMR spectra of cucurbitacins 4-10; electron impact HR-MS for semisynthesized cucurbitacin I (7).
