ABSTRACT

Phosphatidylinositol 4-kinase III β is a cellular lipid kinase pivotal to pathogenesis of various RNA viruses. These viruses hijack the enzyme in order to modify the structure of intracellular membranes and use them for the construction of functional replication machinery. Selective inhibitors of this enzyme are potential broad-spectrum antiviral agents, as inhibition of this

Journal of Medicinal Chemistry

enzyme results in the arrest of replication of PI4K III β -dependent viruses. Herein, we report a detailed study of novel selective inhibitors of PI4K III β , which exert antiviral activity against a panel of single-stranded positive-sense RNA viruses. Our crystallographic data show that the inhibitors occupy the binding site for the adenine ring of the ATP molecule and therefore prevent the phosphorylation reaction.

INTRODUCTION

Phosphatidylinositol 4-phosphate (PI4P) is the most abundant mono phosphoinositide in eukaryotic cell. It decorates the Golgi, trans-Golgi network (TGN), and also has a role at the plasma membrane and endosomes.¹ In addition, PI4P is the precursor for the synthesis of other phosphoinositides, most notably phosphatidylinositol 4,5-bisphosphate (PI(4,5)P₂) – the hallmark of the plasma membrane – and phosphatidylinositol 3,4,5-trisphosphate (PI(3,4,5)P₃), a key secondary messenger molecule. The synthesis of PI4P is carried out by phosphatidylinositol 4-kinases (PI4Ks).^{2, 3} Mammalian genomes contain two types of PI4Ks, type II (PI4K II α and PI4K II β) and type III (PI4K III α and PI4K III β) kinases that share homology with phosphatidylinositol 3-kinases (PI3Ks). Recently, crystal structures were solved for PI4K II α ^{4, 5} and for PI4K III β .⁶

Type II PI4Ks are palmitoylated enzymes stably associated with the membrane. They are present at various endomembranes such as the TGN, early and late endosomes as well as at the plasma membrane.^{7, 8} These enzymes are critical to intracellular trafficking ^{9, 10}, and interact with clathrin adaptor complexes (PI4K IIα with AP-3 and PI4K IIβ with AP1).^{11, 12} In contrast, type III kinases are soluble cytoplasmic proteins that are recruited to the membrane via protein–protein interactions. Efr, YPP1/TTC7 and TMEM150 direct the PI4K IIIα recruitment to

the plasma membrane where it is responsible for PI4P synthesis.^{13, 14} The Golgi resident proteins ACBD3 and GBF1/Arf recruit PI4K IIIβ to the Golgi ^{15, 16} where this enzyme is mostly responsible for the biogenesis of the Golgi pool of PI4P although type II PI4Ks are also contributing to this pool.^{17, 18} The type III PI4Ks are essential host factors for a plethora of single-stranded positive-sense (ss(+)RNA) viruses ¹⁹ and are potential drug targets.

ss(+)RNA viruses hijack PI4Ks to produce membranous organelles (referred to as "membranous webs" or "replication factories") highly enriched in PI4P, which facilitate the assembly of functional viral replication machinery. For example, the Hepatitis C virus (HCV) hijacks both PI4K III α^{20} and PI4K III $\beta^{21, 22}$, whereas various members of the *Picornaviridae* family, including coxsackieviruses and rhinoviruses ²³⁻²⁶, and those of the *Coronaviridae* family ²⁷, were shown to depend on PI4K IIIB. In spite of the broad dependence on PI4Ks, several different molecular mechanisms of hijacking have recently been described. The NS5A protein of HCV directly binds to PI4K III α and stimulates its activity ²⁸, whereas the 3A protein of the Aichi virus hijacks PI4K III^β through interaction with its binding partner, the ACBD3 protein.¹⁵ The recruitment of PI4K IIIB to coxsackievirus B3 replication factories occurs through an unknown mechanism that is independent of ACBD3.²⁹ PI4Ks are therefore potential drug targets as essential host factors for the replication of ss(+)RNA viruses. A possible impediment to these strategies, however, is that genetic inactivation of type III PI4Ks is detrimental for animals.^{30, 31} A window of possibility relies on the fact that RNA viruses require every bit of the cell's PI4K activity (and even up regulate PI4Ks) for replication, whereas partially compromised PI4K activity may be well tolerated in animals, especially if only for a short time period.¹⁹ To clarify whether a therapeutic window exists for PI4K enzyme inhibition, potent and selective inhibitors of the PI4K enzymes are needed.

Journal of Medicinal Chemistry

Although several potent inhibitors of PI4K type III enzymes have been discovered recently, most of them targeted PI4KIII α .^{32, 33} The studies focused on PI4KIII β suffer from a lack of detailed structure–activity relationship (SAR) and structural data, which would allow for a better understanding of the mode of action of these compounds.³⁴⁻³⁶

We present an extensive study on a broad series of novel PI4K III β inhibitors. We show that these compounds are highly selective based on biochemical characterization. We also assess the effects of these inhibitors against selected viruses in cell-based assays. To gain detailed knowledge of the molecular details of their inhibitory mechanisms, we solved the crystal structures of PI4K III β enzyme bound to an archetypical inhibitor and to ATP. These structures revealed the mechanism of PI4K III β enzyme inhibition by these compounds at the atomic level.

RESULTS

Chemistry

We prepared a series of 65 novel compounds based on the screening hit 2a (T-00127-HEV1) discovered by Arita et al.²⁴ We sequentially modified all three parts of the molecule – the amine side chain 1 (Figure 1, in green), bicyclic central core (Figure 1, in red) and aromatic side chain 2 (Figure 1, in blue).

2a (T-00127-HEV1)

Figure 1. Screening hit as a model compound for SAR study.

Firstly, we focused on the effect of diverse modifications of the side chain 1 using the original pyrazolo[1,5-a]pyrimidine central core. Most of the derivatives were prepared starting from the compound 1^{37} by simple nucleophilic substitution (DIPEA, EtOH, 75 °C) of the chlorine atom at position 7 of the bicyclic central core (Scheme 1), which proceeds smoothly with high to excellent yields. An additional series of the inhibitors was prepared by derivatization of the ethylenediamino chain with various substituents (Scheme 2, compounds 3-9). Analogous derivatives 10 and 11 were obtained by acetylation from appropriate starting materials 2f and 2k, respectively.

We also prepared compounds with sulfur and oxygen atom instead of the NH-group at position 7 in order to investigate the influence of putative hydrogen bond with the protein. The thio derivatives were prepared either by reaction with thiourea and subsequent alkylation with chloroethyl morpholine to obtain analogue **13** or by direct nucleophilic substitution using appropriate thiophenol yielding derivative **14**. The oxygen analogue **15** of the parent compound **2a** was prepared also by a nucleophilic substitution under basic conditions (NaH/DMF) (Scheme 3).

Secondly, we turned our attention to the modification of the central bicyclic core. We prepared analogues of the parent compound with imidazo[1,2-a]pyridine (16) (Scheme 4), imidazo[1,2-b]pyridazine (17) (Scheme 5), and pyrazolo[1,5-a][1,3,5]triazine (18) central core (Scheme 7).

The synthesis of imidazo[1,2-a]pyridine derivative started from compound **19**³⁸, which was easily iodinated using NIS (Scheme 4). Suzuki cross-coupling reaction followed by microwave assisted Buchwald-Hartwig reaction with 4-(2-aminoethyl)morpholine yielded the desired analogue **16**. However, this compound is surprisingly unstable and decomposes quite rapidly.

The preparation of the compound **17** started from dichloro derivative **22.**³⁹ Since the reactivity of the chlorine atoms differs significantly, treatment with 4-(2-aminoethyl)morpholine afforded the desired monosubstituted product **23** in high yield. This compound was utilized for subsequent preparation of the methylated derivative **24** (Scheme 5). A number of diverse methylation reactions failed to give this derivative. Finally, the transfer of a methyl group was accomplished

by reacting compound **23** with DABAL-Me₃ (a reactive complex between one molecule of DABCO and two molecules of $AlMe_3$)⁴⁰ under Pd-catalyzed cross-coupling conditions. This way, key intermediate **24** was prepared in moderate 42% yield. Iodination and Suzuki coupling with 3,4-dimethoxyphenyl boronic acid afforded title compound **17** (Scheme 5).

Since the compound **17** exerted interesting inhibitory activity in the PI4KIIIß enzymatic assay, the preparation of analogues with modified substituent at position 6 was the logical further step. The derivative **23** served as a suitable precursor for the preparation of analogues bearing either hydrogen or chlorine atom instead of the methyl group at this position (Scheme 5). The synthesis of the former derivative **(28)** was accomplished by simple hydrogenolysis followed by iodination and Suzuki reaction. The latter compound **(30a)** was obtained in the similar fashion without the hydrogenolysis step. In this case, we prepared also several other related derivatives with this structural pattern summarized in the Scheme 6 using intermediate **29** subdued to Suzuki cross-coupling reactions.

Derivative **32** with the last bicyclic core, pyrazolo[1,5-a][1,3,5]triazine, was obtained starting from bromide **31**⁴¹ by cross coupling reaction with 3,4-dimethoxyphenylboronic acid. Subsequent chlorination followed by immediate substitution of the chlorine atom with the appropriate amine afforded the desired analogue of **2a**, compound **18**, and derivative **33** (Scheme 7.)

Journal of Medicinal Chemistry

Based on our preliminary results from PI4KIIIβ assay, with respect to synthetic feasibility and potential metabolic decomposition, we selected 6-chloro-2-methylimidazo[1,2-b]pyridazine as the most suitable central core and [2-(acetylamino)ethyl]amino group as side chain 1 for further optimization of the aromatic side chain 2. The key intermediate **35** for this study was prepared by by iodination with NIS, giving the compound **34** (Scheme 5), followed by selective nucleophilic substitution of the chlorine at position 8 with 2-aminoethylacetamide.

Majority of compounds form the last series was prepared by Suzuki cross-coupling reaction starting from the compound **35** (Scheme 8).

Another sub-series of derivatives modified in the aromatic side chain was prepared by derivatization of suitable precursors obtained by Suzuki couplings. Firstly, we modified the amino group of the compound **36u**. In particular, we obtained a few acylated derivatives (**37-39**) either by reaction with acyl anhydrides or chlorides (Scheme 9). Subsequently, reaction with isopropylisocyanate afforded the substituted urea derivative **40** and the compounds **41** and **42** were prepared by reductive amination and alkylation of the compound **36u**, respectively (Scheme 10).

We also prepared 3-(3,4-dihydroxyphenyl) derivative **43** by the demethylation of **30a**, albeit in very low yield (Scheme 11). Reduction of the formyl functions in compounds **36e** and **36i** with NaBH₄ gave the corresponding hydroxymethyl derivatives **44** and **45**, respectively, in moderate yields.

In order to introduce highly polar group, the cyano moiety in compound **36h** was successfully reduced to the primary amine **46** which was isolated as its hydrochloride salt.

The analogue of compounds **36a** with hydrogen instead of the chlorine atom at the position 6 of the imidazo[1,2-b]pyridazine core (**47**) was prepared by simple hydrogenolysis of **36a** (Scheme 12).

Finally, the derivative **49** was obtained by ammonolysis of compound **34** and subsequent Suzuki coupling as described in the Scheme 12.

selected 10 compounds, which exerted the highest inhibitory activities against PI4K III β in vitro (Figure 2).

Figure 2. Structures of the selected sub-series of inhibitors. The amine side chains are in green, bicyclic central core in red and aromatic side chain in blue.

We found that the IC₅₀ values for the top 10 compounds were in the range of 50 - 130 nM against PI4K III β . Further, we determined whether the compounds were isoform specific for PI4K III β , a necessity for evaluating therapeutic potential. We have thus used the ADP-Glo kinase assay to measure the IC₅₀ values for two structurally and functionally related enzymes,

PI4K IIIα and PI4K IIα. We found that none of the top 10 compounds inhibited PI4K IIIα and PI4K IIα with an IC₅₀ less than 10 μ M (These data are summarized in Table 1 for the top 10 compounds, and in **Supplementary Results**, Supplementary Table 2 for the remaining 55).

Next we focused on determining the anti-viral activity of the compounds. For this, we used an assay based on the virus-induced cytopathic effect in HeLa cells (in detail in Experimental Methods section). We tested the activity of the compounds against two important members of *Picornaviridae* family, Coxsackievirus B3 (CVB3) and Human Rhinovirus (HRV), and two distinct genotypes of HCV (*Flaviviridae*), genotype 1b and 2a. For each virus tested except for HCV 2a several of the compounds exhibited IC₅₀ values below 1 μ M as summarized in the Table 2 and Supplementary Table 3.

Table 1. Inhibitory activity of selected compounds against members of PI4K family.

Although the correlation between the results from the enzymatic assay and the cell based assay was not very tight, there was a clear rise in antiviral potency as PI4K III β inhibitory activity increased. The sensitivity of various viruses to the inhibition of the PI4K III β showed significant differences. The HCV genotype 1b displayed some sensitivity, whereas the effects of PI4K III β inhibition on replication of HCV 2a were rather limited. The most potent compound in the series was derivative **36t**, which inhibited PI4K III β with IC₅₀ = 54 nM and exerted significant effect in all cell based assays. Derivative **36t** was the most active compound in HVC 2a assay (EC₅₀ = 10.6 μ M) and the second most active against HCV1b (EC50 = 0.087 μ M). Furthermore, this compound showed strong protection against CVB3-induced cytopathic effects in HeLa cells with half maximal effective concentration (EC₅₀) value of 145 nM. This compound was also evaluated in a panel of phosphatidylinositol 3-kinases (PI3Ka, PI3Kb, PI3Kd and PI3Kg). None of this kinases was inhibited with IC₅₀ up to 10 μ M.

Structural analysis of the inhibition mode of PI4K IIIß

To determine how the inhibitors function at the atomic level, we solved the crystal structure of PI4K III β either with an inhibitor or bound to ATP. We selected several inhibitors of archetypical chemical structure and reasonable solubility for crystallographic trials. The best crystals were obtained with inhibitor **49** but still diffracted only to 3.5Å resolution. The structure was solved by molecular replacement using chain A of the crystal structure of PI4K III β with Rab11 (pdb code: ID0L) without the PIK93 inhibitor to reduce bias. Because of the rather low resolution the unbiased Fo – Fc map contoured at 3 σ did not provide enough information to unambiguously place the **49** inhibitor (Supplementary Figure 3). However, the density for the **49** inhibitor (Figure 3a). We have refined the structure to R = 20.89% and R_{free} = 25.16%. To confirm that the result of manual docking and refinement in Coot⁴³ is correct we calculated the R factors for a structure where the **49** inhibitor is rotated by 180° and refined into the Fo – Fc density. The obtained values (R = 21.19% and R_{free} = 26.07%) are significantly worse and argue for correct placement of the ligand.

Crystals with ATP bound diffracted to 3.3Å resolution, the structure was solved in the same way as the structure with **49** inhibitor and refined to R = 18.25% and $R_{free} = 24.41\%$. However, we didn't observe density for the whole ATP molecule, only for the adenine ring (Figure 3b), despite the better resolution. We, therefore, concluded that the ribose ring and the three phosphate groups are disordered in our structure. The density for adenine at 3.3Å, in principle,

allows positioning the adenine ring in multiple orientations. To confirm that the best fit obtained in Coot ⁴³ was the right solution, we compared the structure of PI4K III β with the structure of PI4K II α where the ATP molecule is clearly resolved.⁴ We have used the C-lobes of PI4K II α and PI4K III β for superposition taking advantage of the fact that they are structurally very similar. The superposition revealed that the adenine rings in both structures are in a similar orientation (Supplementary Figure 2), supporting the placement of the adenine ring in the presented structure.

Both **49** and the adenine ring lie in a binding canyon of PI4K IIIβ held in place by a combination of hydrophobic interactions and hydrogen bonds, water bridges surely also contribute (for instance the hydroxyl group of Tyr⁵⁹⁸ and the N6 of the adenine ring are in perfect distance and orientation for a water bridge) but water molecules were not modeled due to limited resolution of our crystal structures (Figure 4a, Figure 4b). Superposition of the two structures revealed that compound **49** and the adenine ring occupy the same pocket (Figure 4c) suggesting that this family of inhibitors function by sterically blocking the binding of the ATP's adenine ring rather than the phosphate moiety and therefore interfering with the course of the reaction.

Figure 4. Structural insight into the inhibition of ATP approach to APT binding site.

- a) Compound 49 in the ATP binding site the inhibitor appears to be strongly bound in the ATP binding site based on strong hydrogen bonds to amino acid residues Val⁶¹³, and Lys⁵⁶⁴ and Glu⁵⁷², and significant structural match with the binding canyon.
- b) ATP bound to PI4K III β a detailed view into ATP binding site residues Glu⁵⁷² and Lys⁵⁶⁴ seem to be in close proximity suggesting existence of electrostatic interaction between these two residues with opposite polarity; this conformation of the protein allows effective binding of the nucleobase due to extensive shape complementarity.

- c) Superposition of ATP and 49 in the biding site, which clearly shows these two ligands occupy the same area of the enzyme and compete with each other at the ATP binding site.
- d) Docking study of the most potent inhibitor in the study derivative **36t** fits nicely into the binding canyon of the enzyme, formed by numerous lipophilic residues. In particular, the aromatic side chain of the inhibitor stays in T-shape conformation to the Tyr⁵⁹⁸ suggesting significant π - π interaction. In comparison with the binding mode of **49**, compound **36t** seems to form a stronger hydrogen bond with Lys⁵⁶⁴ and two additional hydrogen bonds with Val⁶¹³ and Tyr⁴⁰⁰.

Docking study of the inhibitors

We performed docking studies with selected inhibitors to determine putative parts of the inhibitor that could be further modified to enhance the affinity to the enzyme and to explain the results of our structure–activity relationship (SAR) study at the atomic level. The results of our docking study largely explain the outcomes of the SAR study. The conformation of **36t** with the lowest predicted energy fits into the enzyme's ATP binding site and forms three hydrogen bonds with Val⁶¹³ in the hinge region (Figure 4d). The amide oxygen of this residue forms two hydrogen bonds with both nitrogen moieties of side chain 1. The hydrogen atom bound to amide nitrogen of Val⁶¹³ interacts with nitrogen atom of the inhibitor's central bicyclic core, which facilitates effective interaction with the enzyme (Figure 4d). Two additional hydrogen bonds with residues Tyr⁴⁰⁰ and Lys⁵⁶⁴ are responsible for the effect of the sulfonamide moiety (the aromatic side chain) and importance of the amide oxygen atom (the amine side chain), respectively.

DISCUSSION

Selective inhibitors of PI4K III β are critically needed as PI4K III β is a promising target for development of broad spectrum-antiviral agents for treatment of diseases caused by viral pathogens such as SARS, MERS, HCV and HRV. Furthermore, effective inhibitors of this class of enzymes can serve as much-needed tools to understand various processes connected with membrane signaling and mechanisms of membrane trafficking in numerous cellular structures. Therefore, such compounds can revolutionize the treatment of viral diseases and etherpen our knowledge of cell biology of organelles.

Figure 5. Schematic representation of the results of our SAR study.

We show that substitution of all three moieties (amine side chains, bicyclic central core and aromatic side chain) on the parent molecule has significant impact on the activity of this family of inhibitors (Figure 5). Our study suggests that for substitutions the most suitable side chains at position 1 (the amino side chain) are the 2-aminoethyl acetate and the 2-aminoethylacetamide groups. Since the ester substituent is most likely metabolically unstable, we focused our efforts on the amide and the central core of the molecule. These optimizations revealed two important factors: First, simple scaffold hopping significantly influences the activity; thus the derivatives

with imidazo[1,2-b]pyridazine exert higher potency than the members of pyrazolo[1,5alpyrimidine series whereas the compounds with other central cores possess lower affinity towards PI4K IIIB. Second, small variations of the substituent at position 6 of both imidazo[1,2b)pyridazine and pyrazolo[1,5-a)pyrimidine core do not significantly affect the activity. Generally, hydrogen, methyl and chlorine atoms were all tolerated with only marginal differences in their inhibitory activities. We subsequently screened a large series of compounds with aromatic side chain 2 modified to investigate the most suitably decorated arene moiety. Although derivatives with the dimethoxybenzene group were among the most potent inhibitors, the phenyl groups bearing a strong hydrogen bond acceptor, such as sulfonamide or aldehyde, at the meta position relative to the central core significantly contributed to the enhanced affinity towards the enzyme. Using this approach we identified a number of novel inhibitors of PI4K III β with the most interesting compound being **36t** with IC₅₀ = 54 ± 15 nM. This compound displayed antiviral activity against members of both the *Picornaviridae* and the *Filoviridae* families with activities being in the nanomolar level for CVB3 and HCV 1b and in micromolar level for HRVM, and HCV 2a. The results in both enzymatic and antiviral cell-based assays showed the clear superiority over the starting hit T-00127-HEV1 (2a).

Very recently, the first crystal structure of PI4K IIIβ in complex with a non-selective lipid kinase inhibitor, PIK93 was solved by Burke et al.^{6, 44} Our extensive synthetic studies yielding a set of molecular tools now allowed us to solve the structure of PI4K IIIβ bound to a potent and selective molecule, namely compound **49**, which possesses a significantly different structure than PIK93. In addition, we were able to obtain a crystal structure with a bound ATP, even though a significant part of the ATP molecule is disordered in the structure—probably because it would be stabilized by the catalytically important C-terminus of the enzyme, which impedes crystallization

and thus is missing in the crystallized construct.⁶ This crystal structure suggests the correct orientation and electrostatic interactions of the adenine moiety in the hinge region. The superposition of the structure with 49 and ATP clarifies the precise mode of action of this type of inhibitors. They compete with the natural binding site for ATP adenine ring, preventing the binding of ATP and hence inhibiting the lipid phosphorylation reaction. The crystal structures also suggest that the binding of the inhibitor causes conformational changes in the ATP binding site. In particular, residues Glu⁵⁷² and Lys⁵⁶⁴ seem in closer proximity when binding ATP due to a weak electrostatic interaction. However, when the inhibitor 49 is bound, the Lys⁵⁶⁴ residue adopts a conformation that allows for an effective hydrogen bond with one of the methoxy groups of the inhibitor's aromatic side chain. Our docking studies suggest that this interaction can be exploited for the design of inhibitors with significantly enhanced affinity towards the enzyme as demonstrated in the example of the most active compound, **36t**. In the case of compound **36t**, the lysine residue Lys⁵⁶⁴ is significantly attracted by the strongly electronegative oxygen atom of the sulfonamide moiety. The docking studies support the importance of the amide side chain, which can significantly elevate the enthalpic contribution to the interaction of the enzyme and inhibitor. While we cannot explain the specificity of our compounds against PI4K IIIa on the structural level as the PI4K IIIa crystal structure is not available, we can explain why the prepared compounds do not inhibit PI4K IIa. The structural superposition of these two enzymes (Supplementary Figure 3) reveals that from the two most critical residues for inhibitor binding (K564 and E572) only the glutamate is conserved.

CONCLUSION

In conclusion, we present highly potent inhibitors of PI4K III β with excellent selectivity. The most active compound **36t** (IC50 = 54 nM) possesses outstanding selectivity against both the most homologous enzyme - the PI4K III β , and the non-homologues enzyme – the PI4K II α that catalyzes the same reaction. This compound has high potential as exquisite chemical biology tool for efficient studies of PI4Ks in cells and in animal models as well as excellent starting point in the search for broad-spectrum antiviral agents against ss(+)RNA viruses and potential therapeutics of other human diseases. Through our crystallographic and computational studies, we revealed the molecular mechanism of the inhibitors and their disruption of ATP binding. Finally, we explain the role of their structural features for interaction with PI4K III β .

Synthesis of novel inhibitors

General chemical procedures

Melting points were determined on a Büchi melting point B-540 apparatus. Microwave syntheses were carried out in a CEM Discover instrument with a single0-mode cavity and focused microwave heating (microwave power supply 0-300 W, 1 W increments, sealed vessel mode, pressure range 0-20 bar). NMR spectra were measured on a Bruker Avance II-600 and/or Bruker Avance II-500 instruments (600 or 500.0 MHz for ¹H and 150 or 125 MHz for ¹³C) in hexadeuterodimethyl sulfoxide and referenced to the solvent signal (δ 2.50 and 39.70, respectively). Mass spectra were measured on a LTQ Orbitrap XL (Thermo Fischer Scientific) using electrospray ionization (ESI) and a GCT Premier (Waters) using EI. HPLC-MS spectra were obtained on a Shimadzu LCMS-2020 LC-MS. The elemental analyses (summarized in Supplemetary Table 1.) were obtained on a Perkin Elmer CHN Analyzer 2400, Series II Sys (Perkin Elmer) and X-ray fluorescence spectrometer SPECTRO iQ II (SPECTRO Analytical Instruments, Germany). All of the compounds in the series had purity higher than 95% (determined either by elemental analysis or HPLC-MS). Column chromatography and thin-layer
chromatography (TLC) were performed using Silica gel 60 (Fluka) and Silufol Silica gel 60 F_{254} foils (Merck), respectively. Solvents were evaporated at 2 kPa and bath temperature 30 - 60 °C. The compounds were dried at 13 Pa and 50 °C.

General procedure for introduction of the N-substituent to position 7

 Chloro derivative 1^{35} (150 mg, 0.47 mmol) was dissolved in ethanol (5 mL) and DIPEA (0.25 mL, 1.41 mmol) together with an appropriate amine (2 eq.). Reaction mixture was then stirred at 75 °C for 12 h (or until consumption of the starting material). Reaction mixture was then evaporated, the residue was chromatographed (silica gel, 50 g) with an appropriate mobile phase and the solid was recrystallized.

1-(4-(3-(3,4-Dimethoxyphenyl)-2,5-dimethylpyrazolo[1,5-a]pyrimidin-7-yl)piperazin-1-yl)ethanone (**2l**)

Chloro derivative 1 (303 mg, 0.95 mmol) was dissolved in DMF (10 mL) and piperazine (822 mg, 9.5 mmol) was added. Reaction mixture was stirred at r.t. for 3 h and evaporated. Residue was co-evaporated with DMF (3 x 20 mL) and then dissolved in chloroform (70 mL). Organic phase was washed with water (30 mL) and water phase was re-extracted with chloroform (70 mL). Combined organic phases were dried (Na_2SO_4) and evaporated. Crude intermediate was immediately used in the following step. The intermediate was dissolved in CH₂Cl₂ (13 mL) and Et₃N (0.4 mL, 2.9 mmol) at 0 °C. Then acetic anhydride (180 µl, 1.9 mmol) and reaction mixture was stirred at 0 °C for 3 h. Reaction was poured into satd. aq. solution of NaHCO₃ (35 mL) and mixture was extracted with chloroform (2 x 70 mL). Organic phase was dried (Na₂SO₄) and evaporated. Chromatography of the residue on silica gel column (75 g) with ethyl acetate \rightarrow ethyl acetate: toluene: acetone: ethanol (17:4:3:1) afforded the product 21. 4-(2-Hydroxyethyl)morpholine (0.16 mL, 1.3 mmol) was dissolved in DMF (2 mL) and the solution was cooled to 0°C. Sodium hydride (46 mg, 1.14 mmol, 60% dispersion in mineral oil) was added and the reaction mixture was stirred at r.t. for 0.5 h. A solution of chloroderivative 1 (164 mg, 0.52 mmol) in DMF (2 mL + 1 mL for rinsing of the flask) was slowly added during 30 minutes and then reaction mixture was stirred for 2 h. Reaction was quenched with water (1 mL) and evaporated. Residue was taken into ethyl acetate (80 mL) and organic phase was washed with water (2 x 30 mL). Organic phase was dried (Na₂SO₄) and evaporated. Product **15** was isolated by column chromatography (silica gel, 50 g) with ethyl acetate \rightarrow ethyl acetate: acetone: ethanol: H₂O (20:3:1.2:0.8) and crystallized from ethyl acetate. 8-Bromo-3-(3,4-dimethoxyphenyl)-2,6-dimethylimidazo[1,2-a]pyridine (21)

N-iodosuccinimide (2.03 g, 9 mmol) was added to the solution of 8-bromo-3-iodo-2,6dimethylimidazo[1,2-a]pyridine³⁸ (1.35 g, 6 mmol) in DMF (120 mL) and the reaction mixture was stirred overnight at r.t. for 1 h. The reaction mixture was diluted with water (400 mL) and extracted with ethyl acetate (3 x 200 mL). Combined organic phases were dried over sodium sulfate and evaporated. Crude product was then directly used in the next step. The intermediate was dissolved in dioxane (88 mL) and water (22 mL) and sodium carbonate (1.77 g, 16.7 mmol) and boronic acid (1.1 g, 6 mmol) were added. Reaction mixture was three times degassed and purged with argon. To the reaction mixture Pd(dppf)Cl₂ (220 mg, 0.27 mmol) was added in one portion and the mixture was stirred at 95 °C overnight under argon atmosphere. After cooling to ambient temperature the mixture was partitioned between ethyl acetate (400 mL) and brine (200 mL). Organic phase was dried over anhydrous sodium sulfate and evaporated. The crude product was chromatographed on a silica gel column (200 g) in hexanes: ethyl acetate (3:2). It was obtained 975 mg (45%, two steps) of an off-white solid. Analytical sample was obtained after recrystallization from hot ethyl acetate. ¹H NMR (500 MHz, DMSO-d6) δ (ppm): 8.03 (m, 1H, H-5), 7.45 (m, 1H, H-7), 7.14 (d, J_{5'-6} = 8.4, 1H, H-5'), 7.06 (d, J_{2'-6} = 1.9, 1H, H-2'), 7.02 (dd, J_{6'-5'} = 8.4, J_{6'-2'} = 1.9, 1H, H-6'), 3.83 (s, 3H, 4'-OCH₃), 3.80 (s, 3H, 3'-OCH₃), 2.33 (s, 3H, 2-CH₃), 2.24 (s, 3H, 6-CH₃). ¹³C NMR (125 MHz, DMSO-d6) δ (ppm): 149.31 (C-3'), 149.1 (C-4'), 140.5 (C-2), 140.2 (C-8a), 129.2 (C-7), 122.9 (C-3), 122.3 (C-6'), 121.9 (C-6), 121.1 (C-5),

General procedure for Suzuki reaction - preparation of compounds 17, 28 and 30a-c

A suspension of iodine derivative **25**, **27** or **29** (1 eq.) and the corresponding boronic acid (1.1 eq.) in dioxane:1M $K_2CO_3 = 4$:1 was purged repeatedly with argon and Pd(PPh_3)_4 (5 mol%) was added to the mixture. The reaction mixture was degassed again and subsequently stirred at 95-105 °C between 14 and 22 h. The mixture was allowed to cool and diluted with CHCl₃ and H₂O. The layers were separated and the aqueous layer was extracted with CHCl₃; the combined organic phase was dried over Na₂SO₄ and evaporated. The residue was purified by silica gel column chromatography and the product was recrystallized to afford an analytically pure sample.

3-(3,4-Dimethoxyphenyl)-2,6-dimethyl-N-(2-morpholinoethyl)imidazo[1,2-b]pyridazin-8-amine (17)

This compound has been prepared according to the general procedure described for Suzuki reaction. The following reagents, amounts and conditions have been employed: compound **25** (149 mg, 0.371 mmol), 3,4-dimethoxyphenylboronic acid (75 mg, 0.412 mmol), Pd(PPh₃)₄ (21 mg, 0.0182 mmol) in 1M K₂CO₃ (1.2 mL) and dioxane (4 mL). 6-Chloro-3-iodo-2-methyl-N-(2-morpholinoethyl)imidazo[1,2-b]pyridazin-8-amine (29)⁴⁵

To a solution of compound **23** (705 mg, 2.39 mmol) in CH₂Cl₂ (25 mL) and AcOH (1 mL) at 0°C was added N-iodosuccinimide (699 mg, 3.10 mmol) and the reaction mixture was stirred at 0°C for 5 minutes and at rt for 2 ½ h. The mixture was diluted with CH₂Cl₂ (25 mL) and washed with 10% aq. Na₂S₂O₃ (40 mL). The layers were separated and the aqueous layer was extracted with CHCl₃ (2 x 40 mL). The combined layer was subsequently dried over Na₂SO₄ and evaporated to dryness. The crude product was purified by silica gel column chromatography and eluted with Michal 17 which gave compound **29** as an off-white solid. Recrystallization from hot MeOH/CHCl₃ afforded an analytical sample. General procedure for Suzuki coupling reactions – preparation of compounds 36a-u

Round bottom flask was charged with **34** and appropriate boronic acid derivative (1.1eq), 1,4dioxane:water (4:1) and potassium carbonate (3eq). Flask was equipped with stir bar and rubber septum, stirred at RT and degassed 3times and purged with argon. To the reaction mixture $Pd(PPh_3)_4(5 \text{ mol}\%)$ was added in one portion, suspension was refluxed for 2 hours and then stirred at 95 °C overnight under argon atmosphere. Upon completion of the reaction (monitored by TLC) the mixture was cooled to rt, diluted with water and extracted with DCM (3x 50mL). Combined organic phases were dried over sodium sulfate, evaporated and purified by column chromatography.

Compound **36u** (201 mg, 0.52 mmol) was dissolved in DCM (5 mL) followed by addition of DIPEA (0.1 mL, 0.62 mmol). Acetanhydride (0.06 mL, 0.62 mmol) wad then addend dropwise at 0 °C. After the addition the mixture was allowed to warm to rt and stirred overnight. Then it was diluted with DCM, washed with H₂O, dried over sodium sulfate, evaporated to minimal volume and adsorbed onto silica gel. Column chromatography (EtOAc:MeOH - 6:1) afforded the product **37**. Analytical sample was obtained after recrystallization from MeOH:CHCl₃ (10:1) as violet crystals. N-(2-((3-(3,4-Dimethoxyphenyl)-2-methylimidazo[1,2-b]pyridazin-8-yl)amino)ethyl)acetamide (47)

Compound **36a** (272 mg, 0.67 mmol) was dissolved in THF:MeOH (8mL, 1:1) $Pd(OH)_2$ 20 %/C (47 mg, 10 mol %) was added followed by addition of TEA (0.187 mL, 1.35 mmol). Mixture

was stirred under the atmosphere of H₂ in autoclave (5 bar) overnight. Reaction mixture was then filtrated over pad of celite, washed with MeOH and evaporated. Recrystallization from hot MeOH provided the product **47** as an off white solid. Yield: 156 mg (63 %); mp 153.5-154 °; ¹H NMR (500 MHz, DMSO-*d*₆) δ (ppm): 8.05 (t, *J*_{NH-2} = 5.5 Hz, 1H, NH-CO), 7.99 (d, *J*_{6'-7'} = 5.5 Hz, 1H, H-6'), 7.32 (t, *J*_{NH-1} = 5.9 Hz, 1H, 8'-NH), 7.24 (d, *J*_{2''-6''} = 2.0 Hz, H-2''), 7.18 (dd, *J*_{6''-5''} = 8.3, *J*_{6''-2''} = 2.0 Hz, 1H, H-6''), 7.07 (d, *J*_{5''-6''} = 8.3 Hz, 1H, H-5''), 6.12 (d, *J*_{7'-6'} = 5.5 Hz, 1H, H-7'), 3.81 (s, 3H, 4''-OCH₃), 3.78 (s, 3H, 3''-OCH₃), 3.35 (m, 2H, H-2), 3.28 (m, 2H, H-1), 2.43 (s, 3H, 2'-CH₃), 1.81 (s, 3H, NHCOCH₃). ¹³C NMR (125 MHz, DMSO-*d*₆) δ (ppm): 169.9 (C=O), 148.6 (C-3''), 121.9 (C-1''), 113.2 (C-2''), 111.9 (C-5''), 90.1 (C-7'), 55.8 (4'-OCH₃), 55.8 (3'-OCH₃), 41.7 (C-2''), 37.9 (C-1''), 22.9 (CO-CH₃), 14.8 (2'-CH₃). 6-Chloro-3-iodo-2-methylimidazo[1,2-b]pyridazin-8-amine (48)

Compound **34** (141 mg, 4.3 mmol) was diluted with ethanolic ammonia (4.5 mL, 4M) and heated in a microwave reactor at 140 °C for 90 min. After completion of the reaction (monitored by TLC, EtOAc:acetone:EtOH:H₂O 20:3:1:1), the reaction mixture was directly adsorbed on silica gel and purified by column chromatography (hexane/EtOAc 3:2 to 1:1). Recrystallization from hot MeOH afforded greenish crystals of **48**. Yield 108 mg (77 %); mp 244.4-245.7 °C; ¹H NMR (500 MHz, DMSO-*d*₆) δ (ppm): 7.40 (bs, 2H, 8-NH₂), 6.18 (s, 1H, H-7), 2.34 (s, 3H, 2-CH₃). ¹³C NMR (125 MHz, DMSO-*d*₆) δ (ppm): 147.1 (C-6), 144.3 (C-8), 144.0 (C-2), 134.4 (C-9), 94.5 (C-7), 71.9 (3), 14.9 (2-CH₃). 6-Chloro-3-(3,4-dimethoxyphenyl)-2-methylimidazo[1,2-b]pyridazin-8-amine (49)

Compound **48** (176 mg, 0.57 mmol) was dissolved in 1,4-dioxane (8 mL) and (3,4dimethoxyphenyl)boronic acid (124 mg, 0.68 mmol) followed by 1M potassium carbonate solution (2 mL) was added. The reaction mixture was stirred and degassed three times, after which $Pd(PPh_3)_4$ (5 mol %) was added and the mixture was degassed once more, heated up to 90°C and stirred overnight. After cooling to rt the mixture was diluted with water, extracted with EtOAc (2 x 50 mL) and the combined organic phases were dried over sodium sulfate and evaporated. Residue was dissolved in a minimal volume of DCM/MeOH, adsorbed on silica gel and purified by column chromatography (EtOAc). Recrystallization from hot MeOH/CHCl₃ 6:1 afforded analytical sample **49** as an off-white solid. Yield: 145 mg (80%); mp 230.9-231.7 °C; ¹H NMR (500 MHz, DMSO-*d*₆) δ (ppm): 7.31 (bs, 2H, 8-NH₂), 7.21 (d, $J_{2'-6'} = 2.0, 1H, H-2'$), 7.16 (dd, $J_{6'-2'} = 2.0, J_{6'-5'} = 8.3, 1H, H-6'$), 7.10 (d, $J_{5'-6'} = 8.3, 1H, H-5'$), 6.15 (s, 1H, H-7), 3.82 (s, 3H, 3'-O-CH₃), 3.78 (s, 3H, 4'-O-CH₃), 2.42 (s, 3H, 2-CH₃). ¹³C NMR (125 MHz, DMSO-*d*₆) δ (ppm): 148.7 and148.6 (C3'and C4'), 146.5 (C-6), 144.4 (C-8), 137.7 (C-2), 131.0 (C-9), 125.1 (C-3), 122.1 (C-6'), 121.1 (C-1'), 113.2 (C-2'), 112.0 (C-5'), 93.7 (C-7), 55.8 and 55.8 (3'-O-CH₃) and 4'-O-CH₃), 14.7 (2-CH₃). Protein expression and purification

The PI4K III β was expressed and purified using protocols developed in our laboratory. ^{4, 47, 48} Briefly, the protein was affinity purified by using Ni-NTA resin (QIAGEN). Upon cleavage of the 6x His affinity tag the PI4K III β was further purified at Superdex 200 column (GE Healthcare) in 20 mM Citrate, pH =5.5, 200 mMNaCl, 3 mM β -mercaptoethanol. PI4K III β was concentrated to ~5 mg/mL, flash frozen in liquid nitrogen and stored at -80 °C until use.

Crystallization and structure determination

Before setting up crystal drops the protein was supplemented with 5 mM ATP and 2 mM $MgCl_2$ or in the case of the structure with MI103 inhibitor bound, the PI4K III β was incubated over night at 4 °C with 0.5 mM MI103. The crystals grew 5 days at 293 K in sitting drops consisting of a 1:1 mixture of the protein and a well solution (100 mM MOPS/HEPES-Na pH 7.5, 10% *w/v* PEG 4000, 30 mM diethyleneglycol, 30 mM triethyleneglycol, 20% *v/v* glycerol,). The crystals were directly frozen in liquid nitrogen and complete datasets were collected at the MX-14.1 beamLine at BESSY II, Berlin. The structures were solved by molecular replacement

Inhibition of the activity of PI4Ks

The lipid kinase activity was determined by ADP-Glo Kinase Assay (Promega) measuring the amount of ADP produced during the kinase reaction. Reactions were carried out in a total volume of 5 μ l and contained PI4K enzyme (final concentrations for PI4K III β was 4ng/ μ L, for PI4K III α was 2ng/ μ L, and for PI4K II α was 2ng/ μ L) in kinase buffer (20mM TRIS pH 7.5; 5 mM MgCl₂; 0.2% Triton-X; 0.1 mg/mLBSA; 2mM DTT), PI/PS (lipid kinase substrate) in kinase buffer (final concentration = 50 μ M), inhibitors (10 mM stock solutions in DMSO were diluted with kinase buffer to final concentration dependent on inhibitor's activity, *e.g.* 400-0,01; 300-0,0001; 150-0,00001 μ M for PI4K III β), and the reaction was started by adding ATP in kinase buffer (final concentration 100 μ M). This reaction was carried out for 60 min/25°C and the amount of hydrolyzed ATP was measured according to the manufacturer's protocol (add ADP/Glo Reagent to terminate the kinase reaction and deplete the remaining ATP, then add Kinase Detection Reagent to simultaneously convert ADP to ATP and allow the newly synthesized ATP to be measured using a luciferase/luciferin reaction). Luminescence was measured using spectrophotometer TECAN infinite M 1000.

Screening of antiviral activity

The anti-coxsackie activity was measured by determining the extent to which the test compounds inhibited virus-induced cytopathic effect in HeLa cells. Briefly, three-fold serial

Journal of Medicinal Chemistry

dilutions of compounds were added in triplicate in a 96-well plate with 30,000 HeLa cells plated a day ago in DMEM with L-glutamine supplemented with 2% fetal bovine serum (both GE Healthcare, Little Chalfont, UK), 100 U/mL of penicillin, 100 μ g/mL of streptomycin (Sigma-Aldrich, St. Louis, USA). After one hour incubation coxsackie B3 virus (strain Nancy, ATCC, Manassas, USA) was added at multiplicity of infection 0.005 IU/cell. Following three days incubation at 37 °C in 5% CO₂ incubator, the cell viability was determined by addition of XTT solution (Sigma-Aldrich) for 4 hours and the absorbance of newly formed orange formazan solution was measured using Victor X3 plate reader (Perkin Elmer). Drug concentrations required to reduce viral cytopathic effect by 50 % (EC₅₀) were calculated using nonlinear regression analysis from plots of percentage cell viability versus log₁₀ drug concentration using GraphPad Prism v.6.02 (GraphPad Software, La Jolla, USA).

The anti-rhinovirus activity of test compounds was measured in H1-HeLa cells. Compounds were prepared in replicate 3-fold serial dilutions in DMSO (384-well format), and 0.1 μ L of these dilutions were transferred acoustically to assay plates with an Echo instrument. H1-HeLa cells in RPMI medium supplemented with 10% heat inactivated FBS and antibiotics were premixed in batch with mixture of HRV1A, HRV14, and HRV16 at a TCID₉₀ of 4X for each strain. After three day incubation at 33°C, virus-induced cytopathic effects were determined by a Cell-titer Glo viability assay (Promega, Madison, WI).

Anti HCV activity of compounds was determined in multiplex assay using HUH 7-lunet stably replicating I389luc-ubi-neo/NS3-3'/ET genotype 1b replicon and 2aLucNeo-25 cell line encoding a genotype 2a JFH-1 replicon. Cells were maintained in Dulbecco DMEM medium supplemented with GlutaMAX (Invitrogen), 10% FBS (not heat-inactivated), 1mg/mL G-418, Pen-Strep, and non-essential amino acids. Cells were plated into 384-well assay plates with

1600 cells per well and treated with serial dilutions of compounds. Following three day incubation, the activity of Renilla luciferase was quantified using the Dual-Glo luciferase assay system from Promega (Promega, Madison, WI).

Docking

The 3D structures of the docked molecules were built using ACD/ChemSketch 12.01^{50} and the geometry was optimized with MOPAC2012⁵¹ using PM7 method. The necessary format conversions were performed using OpenBabel⁵². The preparation of the pdbqt files was done by standard procedure using AutoDock Tools 1.5.6. The docking runs were performed in AutoDock Vina using the default scoring function. Docking of the ligands into the binding pocket was performed in $24 \times 34 \times 30$ Å search space centered at 25, 33, 0.5 Å and exhaustiveness $100.^{53}$ Since the position of several important residues varies in the two crystal structures, we decided to use flexible docking into the structure with MI103 in order to simulate flexibility of the enzyme (4WAG strucute was used for this purpose). We set Lys⁵⁶⁴ and Tyr⁴⁰⁰ as flexible residues that resulted in obtaining the most reliable results of the docking. The docking results of the top 5 compounds are summarized in Supplementary information.
