Department of Pharmaceutical Manufacturing Chemistry, 21st Century COE Program, Kyoto Pharmaceutical University; 1 Shichono-cho, Misasagi, Yamashina-ku, Kyoto 607–8412, Japan. Received August 2, 2006; accepted September 16, 2006; published online September 21, 2006

( $\pm$ )-Galanthamine (1) was synthesized in excellent yield by applying PIFA-mediated oxidative phenol coupling of *N*-(4-hydroxy)phenethyl-*N*-(3',4',5'-trialkoxy)benzyl formamide (15b) as a key step. Because of the symmetrical characteristics of the pyrogallol moiety in the substrate (15b), the phenol coupling resulted in a sole coupling product except for volatile components from the oxidizing agent. On the basis of the successful results of the above strategy, (-)-galanthamine (1) was synthesized by employing a novel remote asymmetric induction, where conformation of the seven-membered ring in the product of the phenol coupling was restricted by forming a fused-chiral imidazolidinone ring with p-phenylalanine on the benzylic C–N bond of the tri-*O*-alkylated gallyl amino moiety. The conformational restriction and successive debenzylation of the protected hydroxyl groups on the pyrogallol ring caused diastereoselective cyclization to yield a cyclic ether having the desired stereochemistry for the synthesis of (-)-1.

Key words galanthamine; norbelladine; remote asymmetric induction; intramolecular phenol coupling; phenyliodine(III) bis(trifluoroacetate) PIFA; biomimetic synthesis

(-)-Galanthamine (1), an alkaloid isolated from the Caucasian snow drop, Galanthus woronowii,1) and another species of the Amaryllidaceae family, *Lycoris radiate*,<sup>2,3)</sup> has been reported to have many biological activities, e.g., acting as an allosteric modulator of the nicotinic receptor to secrete acetylcholine as well as a competitive inhibitor of acetylcholine esterase.<sup>4)</sup> On the basis of these activities, (-)-1 was developed as a medicine for Altzheimer's disease, which is considered to be caused by the functional deficiency of cholinergic neural networks, and has been already purchased for clinical use in Europe and the United States.<sup>5)</sup> Owing to scarce supplies from the plant source and the significant increase in demand due to the increased average life span in developed countries, the need for a practical total synthesis of (-)-1 and its stable supply has increased. Synthesis of 1, where intramolecular oxidative phenol coupling of norbelladine (2) was adopted to afford narwedine (3), was first attained by Barton and Kirby.<sup>6)</sup> Thereafter, much effort has been made to improve their method<sup>7,8)</sup> since it was accompanied by the successful preparation of an enantiomerically pure form of (-)-1 by using resolutional crystallization of (-)-narwedine (3).<sup>9)</sup> However, the yield of the intramolecular phenol coupling reaction in each synthetic route still remains less than 50%, which hinders the overall yield from reaching a satisfactory level.

While some excellent synthetic approaches of  $(\pm)$ -1 or (-)-1 using intramolecular Heck reaction as a key step have been published recently,<sup>10-20)</sup> such routes required multiple steps and their overall yields are unsatisfactory. Thus, biomimetic approaches *via* the intramolecular phenol coupling reaction still remain a promising strategy in terms of chemical yield and regioselectivities. Based on this background, we have recently published the total synthesis of  $(\pm)$ -1 and the asymmetric synthesis of (-)-1.<sup>21,22</sup> Here, we would like to report the details of the synthesis.

### **Results and Discussion**

A number of Amarylliaceae alkaloids were confirmed to be biosynthesized by the phenol coupling reaction of norbelladine (2), which was derived from L-tyrosine in plants, and the multiple styles of the phenol couplings afford structural diversities of the alkaloids.<sup>23–25)</sup> For example, the coupling between the *p*-position of the phenol part and the o'-position of the catechol portion affords galanthamine (1) alkaloids while p-p' and o-p' couplings respectively afford crinine (4) and lycorine (5) alkaloids. The first synthesis of  $(\pm)$ -1 employed the intramolecular phenol coupling of 2 with potassium ferricyanide but unfortunately preferentially yielded a p-p' coupling product rather than the desired p-o' coupling product due to steric repulsion.<sup>6)</sup> In order to avoid the undesired coupling, the strategy was improved to mask the p'-position with a bromo or trimethylsilyl group. However, chemical yields of the coupling could not be increased to more than 50%.<sup>26-42)</sup> In addition, the coupling reaction using metal oxidants had the practical disadvantages of releasing toxic chemicals as waste reagents, e.g., cyanides from potassium ferricyanide or heavy metal ions.

To overcome these disadvantages in the synthetic strategies of  $(\pm)$ -1, we referred to Koga's procedure where the catechol moiety of **2** was replaced with a pyrogallol group because the symmetrical characteristic of the pyrogallol moiety in the precursor (**6**) made the *p*–*o'* coupling afford the only possible coupling product.<sup>38,39)</sup> Moreover, phenyliodine(III) bis(trifluoroacetate) (PIFA) was chosen as the oxidative reagent for the phenol coupling based on reports that in addition to the coupling product only volatile products, *i.e.*, iodobenzene and trifluoroacetic acid, remained after the PIFA-induced reaction.<sup>33–37,43–49)</sup>

At an initial stage of pretesting, we focused on the PIFAinduced phenol coupling of tri-O-methylated derivatives (7**a**, **b**) of pyrogallol-type norbelladine (6) to synthesize key intermediates 8**a** and 8**b**, and began with the preparation of 7a and 7b. 3,4,5-Trimethoxybenzaldehyde (9) was treated with tyramine in the presence of sodium borohydride to afford 10, which was derived to trifluoroacetamide 7a and formamide 7b. Next, the PIFA-mediated intramolecular phenol couplings of 7a and 7b were attempted and were found to afford good yields (75 and 95%, respectively) of dienone (11a, b) when the reaction was carried out at -40 °C in trifluoroethanol, where low nucleophilicity is believed to increase in the chemical yield of the oxidative coupling (Chart 1).<sup>33–37)</sup>

Herein, we were able to show that the use of the PIFA-mediated phenol coupling, where the substrates had a tri-Omethyl pyrogallol ring instead of a catechol moiety in the norbelladine skeleton, could provide an excellent method for the synthesis of **1**. However, the attempted demethylation of **11a** and **11b** with boron tribromide at -78 °C to afford tetrahydrodibenzofuran derivatives (**8a**, **b**) was unsuccessful because of difficulties in the selective cleavage of methyl ethers and the occurrence of side-reactions such as dienonephenol rearrangement.<sup>50</sup>

Therefore, we considered the synthesis of a substrate (12a) that had no protecting groups on the hydroxyl groups at C-3' and C-5' of the pyrogallol moiety and could be directly transformed to tetrahydrodibenzofuran 8a once the coupling reaction had proceeded smoothly. Namely, the *p*-hydroxyl group of methyl gallate (13a) was first methylated by conventional methods to afford monomethyl ether 13b which was derived to aldehyde 14a via primary alcohol 14b. Reductive amination of 14a with tyramine in the presence of sodium borohydride and successive treatment of the product 12b with trifluoroac-

pyrogallol-type norbelladine (6): R = OH

etamide **12a**. However, solubility of **12a** in trifluoroethanol, the most suitable solvent for PIFA-mediated reaction,<sup>33–37)</sup> was quite poor and the reaction attained in trifluoroacetic acid produced a low yield (12%) of **8a** probably due to side-reactions triggered by the generation of a radical species on the pyrogallol moiety.

Thus, in order to increase solubility in trifluoroethanol and suppress side reactions, the derivatives 15a-g in which the two hydroxyl groups on the pyrogallol moiety of 12a were protected with benzyl (Bn), allyl, methoxymethyl (MOM), or tert-butyldimethylsilyl (TBS) groups were synthesized by first protecting of the hydroxyl groups in 13b. First, monomethyl ether 13b was derived to 16a-d respectively, reduced with lithium aluminum hydride to primary alcohols 17a—d, and oxidized with pyridium chlorochromate or oxygen in the presence of palladium acetate and molecular sieves resulting in aldehydes 18a-d. The aldehydes were treated with tyramine under a reductive condition, *i.e.*, in the presence of sodium borohydride, to afford norbelladine derivatives **19a**—**d**. A formyl group as well as a trifluoroacetyl group were adopted to protecting the secondary amines 19a—d to afford N-protected pyrogallol type-norbelladines 15a—g (Chart 2).

After running the phenol coupling of norbelladine derivatives 15a-g with PIFA in trifluoroethanol -40 °C to afford spirodienones 20a-g (Table 1), it was found that allyl ethers 15c-d, MOM ethers 15e-f, and TBS ether 15g were oxidized to the corresponding siprodienones 20c-g in moderate yields (Table 1, Entries 3—7), and the reaction using benzyl ether 15b as a substrate resulted in the highest yield (Table 1, Entry 2). The formyl group protected secondary amines better than the trifluoroacetyl group in the reactions with 15a and 15b with regard to chemical yield (Table 1, Entries 1, 2). The product 20b was especially easy to crystallize, and was separated mainly by crystallization from a solution of the worked-up residue in ethyl acetate.

Since achieving phenol coupling attainable on a large scale and satisfying economical and environmental issues were crucial, reactions using dibenzyl ether **15b** as a substrate were attempted at 0 °C to room temperature by changing the solvent from trifluoroethanol to other polar solvents and by switching the oxidizing agent from PIFA to phenyliodine(III) diacetate (PIDA) (Table 2). The reaction with PIDA produced a moderate yield of **20b**, compared to the reaction with PIFA (Table 2, Entries 2, 3, 5). As previously predicted,<sup>33–37)</sup> considerable amounts of by-products **21a**—**d** were obtained in cases using acetic acid, acetonitrile, dimethoxyethane, and isopropanol as solvents due to the gen-

eration of a cation (22) or a radical followed by nucleophilic attack of the solvents (Table 2, Entries 4—8). Fortunately, the best yield (85%) was obtained in the reaction conducted with PIFA in trifluoroethanol at room temperature (Table 2, Entry 1). Needless to say, metal oxidants such as manganese(III) acetate and copper(II) acetate gave no productive results.

Next, debenzylation of dienones **20a** and **20b** was performed in order to afford cyclic ethers **8a** and **8b**, respectively, as the resulting products by spontaneous Michael addition of a deprotected hydroxyl group to the dienone moiety. Treatment of **20a** and **20b** with a combination of trifluoroacetic acid and dimethyl sulfide<sup>51–53)</sup> afforded good yields (85 and 81%, respectively) of **8a** and **8b**, respectively (Table 3, Entries 1, 2) in spite of an extended reaction time. Replacing trifluoroacetic acid with a stronger acid such as methanesulfonic acid<sup>54)</sup> resulted in a faster reaction period, but, the chemical yield (62%) was reduced (Table 3, Entry 4) due to undesired dienone-phenol rearrangements.<sup>50)</sup> The use of an odorless sulfide instead of dimethyl sulfide made little difference (Table 3, Entries 3, 5). Deprotection of benzyl ethers with boron trichloride<sup>55–58)</sup> could favorably afford in an excellent yield (95%) of **8b** (Table 3, Entry 6).

Finally, conversion of the cyclic ether **8b** in order to convert it to  $(\pm)$ -1 was attained as follows. The extra phenolic hydroxyl group on **8b** was once transformed to triflate **23**, and successive reduction with palladium acetate in the presence of triphenylphosphine, triethylamine and formic acid afforded narwedine derivative **24**.<sup>59)</sup> Reaction of **24** with L-Selectride<sup>31,32)</sup> followed by reduction of the formyl group to a methyl group with lithium aluminum hydride resulted in a good yield of galanthamine (1) from **8b** (Chart 3).

Our synthetic scheme, where the phenol coupling reaction was especially revised by using a combination of the symmetrical substrate and PIFA, improved the overall yield from the norbelladine derivative (19a) to  $(\pm)$ -galanthamine (1) (44% overall yield, 7 steps).

Herein, it is noteworthy that the successful resolution of galanthamine (1) and narwedine (3) with di-*p*-toluoyl-D-tartaric acid has been reported.<sup>30,60)</sup> Moreover, the synthetic intermediate **3** was found recently to exist as a racemic conglomerate, *i.e.*, a yield of more than 70% of an enantiomerically pure form of **3** could be obtained from a supersaturated solution of ( $\pm$ )-narwedine (**3**) in ethanol and triethylamine, by seeding not only optically pure crystals of **3** but also foreign substances such as (+)- and (-)-galanthamine (1).<sup>61)</sup> Thus, conversion of **24** to **3** was also examined to find an alternative effective synthetic route of optically pure (-)-1. The carbonyl group of **24** was protected with ethylene glycol to give acetal **25**, which was reduced with lithium aluminum hydride, followed by deprotection of the acetal group with acid to achieve an overall good yield (76%) of ( $\pm$ )-**3**.

Encouraged by the success in the racemic synthesis of  $(\pm)$ -1 and to provide an alternative synthesis of 3, which is a key intermediate for the practical synthesis of (-)-galan-

Chart 3. Synthesis of Galanthamine (1) and Narwedine (3)

thamine (1), we next planned to establish a novel route for the asymmetric synthesis of (-)-1 that could circumvent narwedine (3) in view of the severe allergic responses caused. In order to improve racemic synthesis for asymmetric synthesis, the phenolic hydroxyl group should preferentially attack one of the two  $\beta$ -olefinic carbons of the dienone in the intramolecular Michael addition since the symmetrical dienones (20a, b) were converted to racemic mixtures (8a, b) by nonselective intramolecular reaction (Table 3).

Remote asymmetric induction was used, restricting conformation of the seven-membered ring of **20a** by introducing chiral centers similar to Koga who put an alkoxycarbonyl group onto the seven-membered ring for chiral synthesis of (+)-galanthamine (1).<sup>39)</sup> Our strategy was designed so as to introduce another C-N bond on the benzylic position of the gallyl amino moiety of 20a to take advantage of the easily cleavable properties of the benzylic C-N bond and the aza-

Fig. 2. PM3 Calculation of the Intermediate

acetal bond. We decided to link an optically pure  $\alpha$ -amino acid on the benzylic C–N bond of **20a** to afford a chiral imidazolidinone (**A**). Specifically, the conformation of the seven-membered ring of the coupling product **B** would be restricted by the fused-imidazolidinone composed of an amino acid to afford **C** as a single Michael adduct (Chart 4).

Originally, synthesis of chiral 1,3-imidazolidin-5-one and its application to chiral induction was reported by Seebach, who proposed the concept as Self Regeneration of Stereocenters (SRS).<sup>62-64</sup>

Among naturally abundant amino acids, phenylalanine and valine were chosen as the chiral auxiliary to form the fused imidazolidinone because the bulky isopropyl and benzyl groups on amino acid residues would provide promising stereoselectivities. In the beginning, we simply expected that the spontaneous Michael addition after deprotection of  $\mathbb{R}^1$  in **B** would progress diastereoselectively to afford cyclic ether (**C**) with the desired configuration. As expected, PM3 calculation revealed that the most stable conformer of **B** ( $\mathbb{R}^1$ =H,  $\mathbb{R}^2$ =Bn,  $\mathbb{R}^3$ =CF<sub>3</sub>CO), where the chiral imidazolodinone moiety was composed of D-phenylalanine, had shorter distance between the phenolic oxygen atom and C $\beta$ 1 (2.61 Å) than that between the oxygen and C $\beta$ 2 (3.15 Å) (Fig. 2).

Moreover, the calculation showed that the Michael adduct from the former transition state was more stable than that from the latter transition state by 6.7 kcal/mol (Fig. 3). These results supported our expectation that the Michael addition of phenolic hydroxyl groups in **B** bearing a D-amino acid as a chiral auxiliary, predominantly affords a diastereomer that could be led to the desired enantiomers of synthetic intermediates.

Fig. 3. Heat of Formation of the Cyclic Ether (PM3)

On the basis of foregoing, this synthetic strategy began with the reaction of tyramine and *N*-Boc-D-phenylalanine (**26a**) or *N*-Boc-D-valine (**26b**) in the presence of EDC  $\cdot$ HCl and HOBt to afford amides **27a**, **b**. Removal of the Bocgroup of **27a** and **27b** with methanesulfonic acid to afford amines **28a**, **b** and following the formation of a Schiff base with **18a**, and the successive treatment with acid yielded imidazolidinone (**29a**, **b**), respectively, while the acid treatment of **28a** followed by treatment with **9** under acidic condition resulted in **29c**. The diastereoselectivity in the reaction providing **29a** (>98% de) was much higher than those the others (69% de in **29b** and 86% de in **29c**) and the stereochemistry of the major isomers was determined to be *trans* based on the NOESY spectrum. The configuration of the major isomers was also supported by the experimental data in the synthesis of imidazolidinone derivatives, which was reported by Seebach.<sup>62–64)</sup>

The amino group of 29a was next protected with a trifluoroacetyl group to prepare 30a, a substrate of the phenol coupling. The imidazolidinone derivatives 30b and 30c were also prepared from 29b and 29c in order to compare the coupling reactions. Among the intramolecular oxidative couplings of **30a—c** with PIFA in trifluoroethanol, the reaction of **30a** at -40 °C afforded the highest yield of corresponding spirodienone 31a. When the reaction was conducted at room temperature similar to that in Table 2, entry 1, the imidazolidinone moiety seemed to decompose. In addition, the phenol coupling of the compound with a formyl group instead of a trifluoroacetyl group in 30a with PIFA resulted only in a low yield (33%). Although the yield (61%; the best record in our experiments) was not satisfactory in comparison with that obtained in the reaction of **20b**, it was higher than any other reported reactions using norbelladine derivatives as substrates.<sup>26-42)</sup> Because of the high stereoselectivity on forming imidazolidinone and the good chemical yield in the successive phenol coupling, imidazolidinone **29a** with benzyl groups as the protecting groups ( $R^1$ ) and a side chain ( $R^2$ ) of  $\alpha$ -amino acid is considered to be the most suitable synthetic intermediate (Chart 5).

Thus, deprotection of the benzyl group of 31a with boron trichloride at -78 °C afforded an excellent yield (95%) of  $32.^{55-58)}$  In the first strategy of transformation from 32 to (-)-1, we tried to remove the chiral imidazolidinone moiety in the early steps since the presence of a fused ring caused complexities and broadness of the NMR spectra, which interfered with structure analysis. Thus, 32 was first reduced with L-Selectride to afford allyl alcohol 33, where hydrolysis with sodium hydroxide to imine 34 via secondary amine 35 proceeded smoothly at room temperature. Successive reduction of 34 with sodium borohydride and protection of the amino group with a Boc group resulted in 36, with an optical purity of >99% e.e. could be secured by means of a chiral HPLC settled with a DAICEL CHIRALCEL OD column (Chart 6). The high optical purity of 36 confirmed that the intramolecular Michael addition progressed to afford cyclic ether 32 with high stereoselectivity. However, triflation of 36 with triflic

**a**: BCl<sub>3</sub>, **b**: Tf<sub>2</sub>O, pyr., **c**: Pd(OAc)<sub>2</sub>, PPh<sub>3</sub>, Et<sub>3</sub>N, HCO<sub>2</sub>H, **d**: L-Selectride, **e**: KOH, TBAB, **f**: NaBH<sub>4</sub>, **g**: HCO<sub>2</sub>Et, **h**: LiAlH<sub>4</sub>, **i**: NaOH, **j**: (Boc)<sub>2</sub>O anhydride and successive reduction of triflate with a palladium catalyst in the presence of formate<sup>59)</sup> reduced the double bond of the allylic alcohol moiety. In view negative results in the conversion of 32 to (-)-galanthamine (1), we revised the synthetic strategy to deoxygenate the phenolic hydroxyl group of 32 via triflate 37 prior to the reduction of  $\alpha,\beta$ -unsaturated ketone, *i.e.*, cyclic ether **32** was converted to triflate 37 which was reduced with a palladium catalyst in the presence of formate to afford narwedine derivative  $38^{59}$  and then, the conjugated ketone moiety of 38 was reduced with L-Selectride $^{31,32}$  resulting in allyl alcohol **39**. The hydrolysis of 39 under the same conditions adopted in the reaction of 33 did not yield any imine 40 because of the low solubility of the deoxygenated intermediate 39 in an aqueous medium. This was in good contrast with the fast hydrolysis of 33, which could be explained by the higher solubility in an aqueous medium due to the presence of allylic and phenolic hydroxyl groups. Therefore, more drastic conditions were chosen to achieve hydrolysis and the hydrolysis with potassium hydroxide in aqueous ethanol under refluxed conditions in the presence of a phase transfer, tetrabutylammonium bromide (TBAB), finally resulted in imine 40. Imine 40 was reduced with sodium borohydride, and the final N-methylation to galanthamine (1) was attained by N-formylation using ethyl formate and successive reduction of formamide 41 with lithium aluminum hydride. All the spectral and physical data of synthesized (-)-galanthamine (1) were identical with those in publications.

# Conclusions

In conclusion, we succeeded in the synthesis of  $(\pm)$ -1 by using a biomimetic approach, which took advantage of PIFAmediate oxidative phenol coupling of the structurally symmetrical norbelladine derivative **15b**. Moreover, an asymmetric synthesis of optically pure (-)-1, which could circumvent allergenic intermediate **3**, could be attained by using a new type of remote asymmetric induction as a key step. Our synthetic route of (-)-1 provided the highest overall yield (22% from **26a**, 13 steps) among the asymmetric synthesis reported recently.

# Experimental

General Infrared (IR) spectra were recorded on a Shimadzu FTIR-8300 diffraction grating infrared spectrophotometer and <sup>1</sup>H- and <sup>13</sup>C-NMR spectra were obtained on JEOL JNM-AL300, Varian Unity INOVA-400 and Varian GEMINI 200 spectrometers with tetramethylsilane as an internal standard. Mass spectra (MS) were determined on a JEOL JMS-SX 102A QQ or a JEOL JMS-GC-mate mass spectrometer. Specific rotations were recorded on a Horiba SEPA-200 automatic digital polarimeter. Wakogel C-200 (silica gel) (100-200 mesh, Wako) was used for open column chromatography. Flash column chromatography was performed by using Silica Gel 60N (Kanto Chemical Co., Inc.) as a solid support of immobile phase. Kieselgel 60 F-254 plates (Merck) were used for thin-layer chromatography (TLC). Preparative TLC (PTLC) was conducted with Kieselgel 60 F-254 plate (0.25 mm, Merck) or Silica gel 60 F-254 plate (0.5 mm, Merk). Unless purification with silica gel gave a pure enough compound, the compounds were further treated with a recycle HPLC (JAI LC-908) on GPC column (JAIGEL 1H and 2H). In the case it is possible, diastereomeric mixtures were also separated by a recycle HPLC (JAI LC-908) on silica gel column (Kusano Si-10) after the purification mentioned above.

*N*-(4-Hydroxy)phenethyl-*N*-(3,4,5-trimethoxy)benzylamine (10) Tyramine (4.20 g, 30.6 mmol) was added to a solution of 9 (5.00 g, 25.5 mmol) in methanol (50 ml) and the mixture was stirred for 2 d at room temperature. After cooling the mixture at 0 °C, sodium borohydride (1.04 g, 27.5 mmol) was added to the reaction mixture, which was stirred for 24 h at room temperature. After the reaction, the reaction mixture was evaporated and crystal-lized from methanol to afford **10** (7.77 g, 98%) as colorless crystals; mp 161—163 °C. <sup>1</sup>H-NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$ : 2.77 (2H, t, *J*=6.9 Hz, Ar-CH<sub>2</sub>-CH<sub>2</sub>-N), 2.89 (2H, t, *J*=6.9 Hz, CH<sub>2</sub>-CH<sub>2</sub>-N), 3.74 (2H, s, Ar-CH<sub>2</sub>-N), 3.80 (6H, s, OCH<sub>3</sub>×2), 3.82 (3H, s, OCH<sub>3</sub>), 6.50 (2H, s, Ar-H), 6.70 (2H, d, *J*=8.5 Hz, Ar-H), 7.03 (2H, d, *J*=8.5 Hz, Ar-H). <sup>13</sup>C-NMR (50 MHz, CDCl<sub>3</sub>)  $\delta$ : 35.3, 50.8, 54.4, 56.4, 61.2, 105.4, 115.9, 130.0, 131.2, 135.5, 137.2, 153.5, 155.0. (±)-Narwedine (3) A suspension of lithium aluminum hydride (9.95 mg, 0.262 mmol) in tetrahydrofuran (1.0 ml) was added to a solution of 25 (30.0 mg, 0.087 mmol) in tetrahydrofuran (0.5 ml) and the mixture was stirred for 24 h. After the reaction, a saturated aqueous solution of sodium sulfate was added to the reaction mixture, which was extracted with chloroform. The organic layer was washed with a saturated aqueous solution of sodium chloride, dried over sodium sulfate and evaporated. The residue was dissolved in tetrahydrofuran (1 ml), to which 1 M hydrochloric acid was added, and the mixture was stirred for 24 h at room temperature. After the reaction, the reaction mixture was extracted with chloroform. The organic layer was washed with saturated aqueous solution of sodium chloride, dried over sodium sulfate, and evaporated. The residue was purified by silica gel column chromatography (chloroform: methanol=10:1) to afford  $(\pm)$ -3 as colorless crystals (20.6 mg, 83%); mp 198-199 °C (ethyl acetate) [lit. mp 188—190 °C].<sup>17)</sup> <sup>1</sup>H-NMR (400 MHz, CDCl<sub>3</sub>) δ: 1.84—1.89 (1H, m), 2.28 (1H, dt, J=13.2, 3.5 Hz), 2.45 (3H, s, NMe), 2.75 (1H, dd, J=17.9, 3.8 Hz), 3.19 (3H, m), 3.75 (1H, d, J=15.4 Hz, A part of AB type), 3.85 (3H, s, OMe), 4.10 (1H, d, J=15.4 Hz, B part of AB type), 4.73-4.75 (1H, m), 6.05 (1H, d, J=10.4 Hz), 6.66 (1H, d, J=8.2 Hz, Ar-H), 6.70 (1H, d, J=8.2 Hz, Ar-H), 6.95 (1H, d, J=10.4 Hz,). <sup>13</sup>C-NMR (100 MHz, CDCl<sub>3</sub>)  $\delta$ : 33.6, 37.7, 42.8, 49.3, 54.5, 56.4, 61.0, 88.3, 112.2, 122.3, 127.5, 129.8, 130.9, 144.3, 144.7, 147.3, 194.8.
