Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

Abstract

Described here is an advanced, general method for purely chemical dynamic thermodynamic resolution (DTR) and *S/R* interconversion of unprotected tailor-made α -amino acids (α -AAs) through intermediate formation of the corresponding nickel(II)-chelated Schiff bases. The method features virtually complete stereochemical outcome, broad substrate generality (35 examples) and operationally convenient conditions allowing for large-scale preparation of the target α -AAs in enantiomerically pure form. Furthermore, the new type of non-racemizable axially chiral ligands can be quantitatively recycled and reused, rendering the whole process economically and synthetically attractive.

Introduction

Interest in the development of new methods for preparation of tailor-made α -amino acids (α -AAs) in enantiomerically pure form is at an all-time high, because of their ever-increasing applications in pharmaceutical and healthcare industries.^{1,2} In particular, the area of peptide-based drugs is the most promising and fast-growing sector in the new pharmaceuticals design. Currently, substitution of a **ACS Paragon Plus Environment**

The Journal of Organic Chemistry

natural α -AA by an unnatural, tailor-made analog in polypeptide drugs is a widely used approach to overcome the disadvantages related to poor chemical and pharmacokinetic profiles of natural polypeptides. High pharmaceutical potential of unnatural, tailor-made α -AAs can be best illustrated using examples of the most recently developed very successful drugs. For instance, telaprevir (1) (Figure 1) is the all-tailor-made α -AAs tetra-peptide possesses remarkably strong anti-HCV activity.³ Degarelix (2), the poly-peptide containing six key tailor-made α -AA residues, is an exceptionally selective gonadotrophin releasing hormone (GnRH) receptor antagonist, prescribed for the treatment of advanced prostate cancer.⁴ Both drugs were developed starting form all-natural AAs peptides using tailor-made α -AA scan approach. Another notable example of a powerful peptide-based drug is carfilzomib (3), which was developed from the natural product epoxomicin.⁵ Substitution of phenylalanine for tailor-made homophenylalanine resulted in a remarkable activity of **3** as chymotrypsin-like protease inhibitor. Furthermore, besides peptide-based drugs, there are a number of important small-molecular-weight drugs containing fragments of tailor-made α -AAs, for example, DDP-IV inhibitor saxagliptin (**4**) and antiepileptic agent lacosamide (**5**) (Figure 1).^{6,7}

Figure 1. Structures of current representative pharmaceuticals containing tailor-made α -AAs.

ACS Paragon Plus Environment

Considering the pharmaceutical potential of unnatural, tailor-made α -AAs, the development of new approaches for preparation of structurally varied AAs in enantiomerically pure form has been one of the most actively studied areas of organic synthesis.^{8,9} The current wealth of synthetic methodology allows for preparation of virtually any structurally or stereochemically complex α -AAs. On the other hand, the aspects of practicality and cost of target α -AAs have often been neglected rendering the known chemical methods prohibitively expensive even for gram-scale preparations.¹⁰ Consequently, the cost-per-structure issue is currently the major key factor in the quality assessment of a new synthetic method. Particularly, high yields and degree of stereocontrol accessible under operationally convenient conditions, such as an easily maintainable temperature and the use of air-and moisture-stable reagents, are unarguably essential requirements of a truly practical synthetic method.¹¹

Considering the subject of preparation of enantiomerically pure α -AAs from the stand point of practicality, it might be a general consensus that resolution of racemic α -AAs (*rac*- α -AAs), in particular, dynamic resolution is the most economically feasible approach, including dynamic kinetic resolution (DKR) and dynamic thermodynamic resolution (DTR). DKR of *rac*- α -AAs is mainly dominated by the enzymatic approaches, while chemical methods, despite the intellectual brilliance and reaction ingenuity, play a rather ornamental role. For example, state-of-the-art enzymatic approach (Scheme 1) can involve up to three biocatalytic reactions including racemization, kinetic resolution and deprotection stages.¹² However, the whole process requires a purely chemical step for proper protection of the starting *rac*- α -AAs **6**.

Scheme 1. General biocatalytic approach for DKR of protected rac-a-AAs derivatives

In the field of non-enzymatic, chemical DKR of $rac-\alpha$ -AAs,^{13,14} one of the outstanding methods is a catalytic alcoholytic opening of oxazol-5(4H)-ones (Scheme 2).¹⁵ This approach makes use of very high C-H acidity and reactivity of oxazolones **11**, **12** allowing for quite efficient racemization and catalytic ring opening under very mild conditions. This process also necessitates special preparation of oxazolones **11**, **12** and deprotection of the intermediate derivatives **14**.

Scheme 2. An example of chemical approach for DKR of protected rac-a-AAs derivatives

Nevertheless, the direct dynamic resolution of unprotected α -AAs is difficult to realize, and there are only two literature precedents based on the application of chiral ligands **15** and **16** can achieve this (Figure 2).¹⁶ Both methods are purely chemical and make use of in situ formation of the corresponding Schiff bases starting form unprotected α -AAs. While these reports have made a

significant methodological breakthrough, the synthetic value of ligands **15** and **16** is rather limited due to the lack of substrate generality and incomplete stereochemical outcome.

Consistent with our longstanding interest in the development of synthetic methods for preparation of tailor-made amino acids,¹⁷ we have been developed a modular approach to the design of new ligands and the corresponding Ni(II)-complexes for general asymmetric synthesis of α - and β -AAs.¹⁸ One of the major breakthroughs in this research is the development of specially designed, axially chiral ligands (S)- and (R)-17 (Figure 2) and their use for DTR of several natural proteinogenic α -AAs based on thermodynamic equilibration of diastereometric products.¹⁹⁻²¹ Here we report a detailed account of our research on the application of (S)- and (R)-17 for general DTR of unprotected rac- α -AAs. Furthermore, we demonstrate that ligands (S)- and (R)-17 can also be used for S/R interconversion of unprotected α -AAs, underscoring synthetic range and flexibility of this approach. In the present work we focus entirely on unnatural, tailor-made α -AAs of high pharmaceutical potential. We demonstrate a remarkable generality of this method using 35 examples of polyfunctional, structurally varied α-AAs and provide detailed mechanistic rationale for the observed thermodynamically controlled stereochemical outcome. The chemical process presented in this paper features virtually complete yields and diastereoselectivity, fully recyclable chiral ligands (S)- and (R)-17 and operationally simple reaction conditions.

Figure 2. Structural types of known 15, 16 and new 17 ligands for direct dynamic resolution of

unprotected α-AAs.

Results and Discussion

Synthesis of axially chiral ligands. Synthesis of ligands (*S*)- and (*R*)-17 (Scheme 3) is very straightforward two-step process involving high-yielding reactions. First step, the acylation of 2-amino-5-chlorobenzophenone 18 with bromoacetyl bromide 19, is conducted at ambient temperature affording the intermediate amide 20 in high yield. The second step consists of selective *N*-alkylation of enantiomerically pure axially chiral secondary amine 21 which proceeds at room temperature with quantitative yield. Enantiomerically pure amines (*S*)- and (*R*)-21 can be reliably prepared on a large scale by resolution of inexpensive racemic 21 with *L*-(-)-tartaric acid.²² The whole procedure is noticeably very simple, operationally convenient and can be reproduced on >300 g scale. For the large-scale synthesis, this route can be conducted as one-pot process without purification of amide 20 affording ligands (*S*)- and (*R*)-17 of, at least, 85% chemical purity, which can be directly used for the DTR or *S/R* interconversion of tailor-made α -AAs.

Scheme 3. Synthesis of axially chiral ligands (S)- and (R)-17

Application of ligands (S)- and (R)-17 for DTR of tailor-made $rac-\alpha$ -AAs. With the aim to optimize the reaction conditions and understand the mode of stereochemical preferences, we conducted a series of experiments carefully monitoring the reaction composition over time using HPLC analysis. As a representative example, we selected multifunctional rac-6-Cl-tryptophan 22a (Figure 3). The reaction between ligand (R)-17 and unprotected rac-22a was conducted in methanol ACS Paragon Plus Environment

at 40 °C, using Ni(OAc)₂'4H₂O and K₂CO₃ as a base. As one can see from Figure 3, on the early reaction stage the ratio between diastereomers $(R_a)(S_c)$ -23a and $(R_a)(R_c)$ -23a was about 3:1, indicating rather low kinetic stereoselectivity. However, with the reaction progress over time, the amount of major diastereomer $(R_a)(S_c)$ -23a was rapidly increasing while the quantity of minor stereoisomer $(R_a)(R_c)$ -23a was correspondingly decreasing. Thus, at nearly 90% conversion of starting ligand (R)-17, the ratio $(R_a)(S_c)$ -23a/ $(R_a)(R_c)$ -23a was about 9:1, clearly suggesting that the former diastereomer is thermodynamically preferred product. Final thermodynamic control was achieved after almost 48 h furnishing diastereomers $(R_a)(S_c)$ -23a and $(R_a)(R_c)$ -23a in a ratio of 99.54:0.46 (see Table S1 in the Supporting Information). Major product $(R_a)(S_c)$ -23a was isolated in diastereomerically pure form (>99% de) with excellent 97% yield. It can be reasonably assumed that under the reaction conditions minor diastereomer $(R_a)(R_c)$ -23a undergoes base-catalyzed α -epimerization, *via* the corresponding intermediate enolate, to form the thermodynamic product $(R_a)(S_c)$ -23a (see Figure S1 in the Supporting Information).

Figure 3. Reaction of ligand (*R*)-17 with *rac*-6-Cl-tryptophan 22a.

ACS Paragon Plus Environment

The Journal of Organic Chemistry

Additional optimization of the reaction conditions revealed that the thermodynamic control can be considerably accelerated at elevated temperatures; in particular, 70 °C was found most optimal, as virtually no byproducts were detected in the crude reaction mixture. Furthermore, we found that only 10% excess of both the *rac*- α -AA and Ni(OAc)₂·4H₂O is needed for optimal reaction rates and complete consumption of the starting ligand (*R*)-17. Using these standard conditions, we advanced to the substrate generality study and the most representative results are collected in Table 1.

the crude reaction mixtures. ^d Reactions rate was relatively high; therefore the reactions were conducted at 40 °C. ^e The reaction was performed with 500mg of ligand (*S*)-17 for the following disassembly process. ^f The reaction was reproduced on large-scale starting with 10 g of ligand (*S*)-17 (97% yield, >99:1 dr).

Phenylalanine (Phe) derivatives represent one of the most frequently used types of tailor-made α -AAs for modification of natural peptides.^{4,5} Therefore, we decided to study relatively large series of various phenylalanine derivatives rac-22b-m. The reactions of ligand (S)-17 with unprotected ortho-substituted phenylalanines rac-22b-e gave rise to products $(S_a)(R_c)$ -23 with very good stereochemical outcome (entries 2-5). The level of diastereoselectivity, ranging from 92 to 99% de, was rather in the line with the optimized reaction (entry 1). On the other hand, the variable yields may be attributed to generally lower reaction rates due to the steric effect of the *ortho*-substituents. Quite agreeably with assumption, the yields obtained in the reactions of ligand (S)-17 with *meta*-substituted derivatives *rac*-22f-h were truly excellent; albeit the diastereoselectivity was a bit lower (entries 6-8). Virtually quantitative yields were obtained also in the reactions of *para*-substituted phenylalanines *rac*-22i-m with ligand (S)-17 (entries 9-13), with an exception of para-acetyl group containing rac-22m (78%, entry 13). In this case the lower yield might be explained by rather special physicochemical properties of the products due to very polar nature of acetyl moiety. Importantly, in this series of tailor-made phenylalanine derivatives neither electronic nor steric properties of the substituents did not show any apparent effects on the stereochemical outcome of the reactions. In particular, we would like to mention excellent stereochemical outcome observed in the reactions of ligand (S)-17 with rac-22d,g (entries 4, 7), bearing free hydroxyl group, which usually require proper protection in the corresponding enzymatic methods. Another example worth mentioning is the DTR of *para*-Cl-phenylalanine *rac*-22j, used in the design of degarelix (2) (Figure 1).⁴ Using our method this α -AA can be prepared quite efficiently (yield 99% with 98% de;

Another structural group of α -AAs used in this study are poly-aromatic derivatives represented by β -naphthylalanine rac-22n, used in the design of degarelix (2) (Figure 1)⁴ and para-(phenyl)-phenylalanine rac-220 (entries 14, 15). The corresponding reactions with ligand (S)-17 proceeded with excellent stereochemical outcome allowing preparation of target products $(S_a)(R_c)$ -23n,o in diastereometrically pure form with 98% yield. Tailor-made α -AAs containing aromatic heterocyclic moieties are usually quite formidable targets, but they are in a great demand as key structural features in the peptide-base drugs design.⁴ To explore this special structural type, we selected four α -AAs rac-22p-s and performed their reactions with both (S)- and (R)-17. The results obtained were exceptionally good in terms of both diastereoselectivity and chemical yields (entries 16-19). One more unusual and synthetically challenging structural type of tailor-made α -AAs is represented by allyl group containing *rac*-22t, u (entries 20, 21). Gratifyingly, we found that the reactions of unprotected rac-22t, u with ligand (R)-17 proceeded quite smoothly affording products $(R_a)(S_c)$ -23t,u with excellent stereochemical outcome. Another relatively large group of tailor-made α -AAs studied in this work, represents aliphatic derivatives containing various linear as well as sterically constrained cyclic fragments. For example, unprotected rac-22v,w (entries 22, 23), bearing cyclo-propyl and -hexyl rings, reacted with (S) configured ligand 17 exceptionally well, furnishing major diastereomers $(S_a)(R_c)$ -23v, w with excellent yields and stereoselectivity. On the other hand, the reactions of α-AAs rac-22x-z, bearing linear alkyl groups (entries 24-26), and rac-22aa, possessing phenethyl moiety (entry 27), also gave satisfactory yields and stereoselectivity. Of particular interest was the reaction of α -AA rac-22bb containing sterically constrained cyclo-butyl ring (entry 28). The outcome was quite satisfactory affording diastereomer $(S_a)(R_c)$ -23bb in very good yield and diastereomeric excess. Finally, we believe it is very important to mention a few less successful results pointing to some limitations of this method. For example, the reaction of sterically

The Journal of Organic Chemistry

bulky *rac-tert*-leucine **22cc** with ligand (*R*)-**17** proceeded at slow rate and with far form incomplete thermodynamic control (entry 29). On the other hand, *rac*-phenylglycine **22dd** (entry 30) reacted with ligand (*S*)-**17** at rather good rate but with noticeably lower diastereoselectivity. Taking advantage of the nearly perfect stereochemical outcome in the case of *cyclo*-hexane containing AA *rac*-**22w** (entry 23), we performed large-scale experiment using 10 g of the starting ligand (*S*)-**17**. The reaction proceeded without any complication furnishing diastereomerically pure $(S_a)(R_c)$ -**23w** with 94% isolated yield.

To conclude this part of the study, we would like to emphasize that axially chiral ligands (*S*)- and (*R*)-17 were evidently proven to be very efficient reagents for direct DTR of various unprotected tailor-made rac- α -AAs. In the most of cases reported in Table 1, the reactions took place under operationally convenient conditions affording the major products with synthetically valuable diastereoselectivity and chemical yields. It should be mentioned that due to the significant differences in physicochemical properties between major (S_a)(R_c)-23 and minor (S_a)(S_c)-23 diastereomers the purification of the former can be readily achieved by recrystallization or regular gravity-driven column chromatography.

Application of ligands (*S*)- and (*R*)-17 for *S/R* interconversion of tailor-made α -AAs. Inspired by the exciting results obtained for the DTR of tailor-made *rac*- α -AAs, we decided to explore an additional methodological opportunity such as *S/R* interconversion of α -AAs. Compared to the DTR of *rac*- α -AAs, conversion of (*S*)- α -AAs to (*R*) enantiomers and vice versa, is obviously of much lesser general use for production of enantiomerically pure α -AAs. However, in some cases, such as utilization of undesired enantiomers, availability of the *S/R*-interconversion method can be of critical practical importance. Furthermore, a synthetic concept allowing the use of the same chiral ligands, reagents and even conditions to pursue simply by choice either DTR or *S/R* interconversion, has conduct the present study.

As we did in the research on DTR, we decided to investigate first the reaction progress and the chemical composition over time. As a model reaction, we chose (*R*)-6-Cl-tryptophan **22a** as the expected products $(R_a)(S_c)$ -**23a** and $(R_a)(R_c)$ -**23a** were already characterized and monitored by HPLC (Table S2). The reaction of (*R*)-**22a** with ligand (*R*)-**17** was conducted under the standard conditions: heating reagents in methanol at 40 °C. Composition of starting ligand (*R*)-**17** and products $(R_a)(S_c)$ -**23a** and $(R_a)(R_c)$ -**23a** were carefully monitored by HPLC analysis; the results are presented in Figure 4.

Figure 4. Reaction of ligand (*R*)-17 with (*R*)-22a; progress and stereochemical outcome over time.

As expected, diastereomer $(R_a)(R_c)$ -**23a** was a kinetic product on the early reaction stage. From the data obtained, it was apparently clear that the rate of $(R_a)(R_c)$ -**23a** formation was a bit faster than the rate of its based-catalyzed α -epimerization (*via* intermediate enolate) to form the thermodynamic product $(R_a)(S_c)$ -**23a**, rendering $(R_a)(R_c)$ -**23a** as a major product until about 50% consumption of the starting ligand (R)-**17**. However, quite rapidly the relative amounts of $(R_a)(R_c)$ -**23a** were gradually decreasing, while diastereomer $(R_a)(S_c)$ -**23a** became a major product after about 1.5 h of the reaction time. Ultimately, after 33 h under full thermodynamic control, kinetic $(R_a)(R_c)$ -**23a** was virtually **ACS Paragon Plus Environment**

completely transformed to $(R_a)(S_c)$ -23a with the final ratio of 99.63:0.37 (see Table S2 in the

Supporting Information).

With these data in hand, we next proceeded to study the substrate generality of *S*/*R*-interconversion method; some selected results are presented in Table 2.

^a Reaction conditions: (*S*)-17 or (*R*)-17 (0.176 mmol), (*S*)- or (*R*)- α -AAs 22 (0.194 mmol), Ni(OAc)₂·4H₂O (0.194 mmol), K₂CO₃ (1.06 mmol) were refluxed in methanol (6 mL) for 2-28 hrs. ^b Combined yield of isolated product 23. ^c Determined by LC/MS analysis of the crude reaction mixtures. ^d Reactions conducted at 40 °C. ^e The reaction was performed with 500mg of ligand (*R*)-17 for the following disassembly process.

First, we reproduced the described above procedure using optically pure AA 22a and ligand 17 of both opposite absolute configurations. The reaction of ligand (*S*)-17 with (*S*) configured 22a gave virtually identical stereochemical outcome allowing preparation of product (S_a)(R_c)-23a with virtually complete chemical yield and diastereoselectivity (entry 1 vs. 2). Similarly excellent results were obtained in the reactions of 4-Cl-Phe (*S*)-22j (entry 3) and 4-Me-Phe (*S*)-22ee (entry 4) with ligand (*S*)-17 furnishing diastereomerically pure products (S_a)(R_c)-23j,ee. Interesting example of disubstituted derivative, 3,4-difluoro-Phe 22ff is presented in entry 5. In this case the reaction of (R)-22ff with (R)-17 resulted in a complete inversion of the α -configuration giving rise to complex (R_a)(S_c)-23ff with excellent yield and stereoselectivity. Sterically bulky β -Ph-Phe (*S*)-22gg reacted with ligand (*S*)-17 at relatively high rate, however, the diastereoselectivity was less than expected (entry 6). Three more examples featuring (R)-to-(S) conversion of thienylalanine (R)-22hh (entry 7), propargylglycine (R)-22ii (entry 8) and (S)-to-(R) transformation of n-butylglycine (S)-22y (entry 9) provide some additional evidence of wide structural generality of this method.

Disassembly of products 23, isolation of free amino acids 22 and recovery/reuse of chiral ligands 17. To demonstrate the isolation of free α -AAs from products 23, we selected *para*-Cl-Phe (*R*)-22j (Scheme 4) of known pharmaceutical importance⁴, quite interesting long-chain *n*-butyl (*R*)-24y and sterically constrained *cyclo*-butyl (*R*)-24bb containing AAs, as well as an example of heterocyclic thienylalanine (*S*)-22hh, representing both the DTR and *S*/*R*-interconversion approaches. Disassembly of Ni(II) complexes of amino acid Schiff bases is usually conducted under acidic conditions with an option to isolate the target free amino acid or conduct its *N*-derivatization in situ.^{8h-k} Taking advantage of truly exceptional stereochemical outcome (DTR approach; Table 1, entry 10) obtained in preparation of (*S*_a)(*R*_c)-23j, we performed its disassembly without any additional purification. Due to a relatively high solubility of Ni(II) complex (*S*_a)(*R*_c)-23j in methanol (Scheme 4), its disassembly under the action of 6 *N* HCl occurred at very high rate affording

enantiomerically pure (>99% ee) free (*R*)-4-Cl-phenylalanine **22j** in excellent isolated yield (95%). Similarly, diastereomerically pure Ni(II) complexes $(S_a)(R_c)$ -**23y**, $(S_a)(R_c)$ -**23bb**, obtained using DTR and $(R_a)(S_c)$ -**23hh**, using the *S*/*R*-interconversion approach, were disassembled to furnish free amino acids (*R*)-**22y**, (*R*)-**22bb** and (*S*)-**22hh** in >90% yields.

Scheme 4. Disassembly of $(S_a)(R_c)$ -23j, y, bb and $(R_a)(S_c)$ -hh: isolation of the target AAs (R)-22j,

y, bb and (S)-22hh, recycling, and reuse of the chiral ligands (S)-17 and (R)-17

It should be specially emphasized that along with the target AAs (*R*)-22j, y, bb and (*S*)-22hh, ligands (*S*)-17 and (*R*)-17 were virtually quantitatively (>95% yield) recovered. Without any additional purification ligands (*S*)-17 and (*R*)-17 can be successfully reused for DTR or *S*/*R* interconversion of any target α -AA. One may agree that convenient recycling and reuse of the chiral

ligands **17** render the present approach economically very attractive surpassing efficiency and practicality of biocatalytic approaches.

Assignment of the absolute configurations and rationale for the observed stereochemical outcome. Absolute configuration of α -AA residues in products $(S_a)(R_c)$ -23j, y, bb and $(R_a)(S_c)$ -23hh was made by comparison of the optical properties of isolated AAs (R)-22j, y, bb and (S)-22hh with the literature data. Furthermore, we performed a crystallographic analysis of Ni(II) complex 23j, confirming its $(S_a)(R_c)$ configuration (see CIF and Figure S2 in the Supporting Information). Stereochemistry of other products 23a-i, k-x, z-aa, cc-gg and ii was assigned based on their matching spectroscopic and optical properties with complexes $(S_a)(R_c)$ -23j, y, bb and $(R_a)(S_c)$ -23hh.

Crystallographic structure of Ni(II) complex $(S_a)(R_c)$ -23j, containing (R)-4-Cl-Phe moiety, has several unexpected, rather unique features. First of all, what is quite striking, there are no any stereochemical contacts between the chiral auxiliary's bisnaphthyl frame and the amino acid residue. What is evident from the structure is that the observed preference for the (R) absolute configuration of the (R)-4-Cl-Phe moiety is not directly controlled by the chiral auxiliary. Another prominent peculiarity of crystallographic structure of $(S_a)(R_c)$ -23j is a notably severe twisting of the chelate rings around the Ni(II). Thus, while the coordinating to Ni(II) three nitrogen and one oxygen atoms are nearly perfectly coplanar, the chelate rings A, B, and C (Figure 5) are noticeably puckered out of this plane. In particular, the ring A is puckered up above the plane showing the torsion angle $(N-Ni-N-CH_2)$ of 36.10°. By contract, the ring **B** is puckered down out of this plane with torsion angle (N-Ni-N-C) of -30.19° . Subsequently, the ring C is puckered up above the plane. As a result of this sterically congested arrangement, the benzophenone phenyl ring is skewed by -70.65° and located right below the chelate ring C. The distance between the phenyl ortho-hydrogen and the hydrogen of amino acid C-H group is only 2.38 Å, strongly indicating that the position of 4-Cl-benzyl group up and away from the phenyl is the only stereochemically feasible option. Based

The Journal of Organic Chemistry

on these structural features, one can assume the following mode of the observed stereocontrol. First, the helical chirality of the bisnaphthyl moiety induces the chiral puckering of the three chelate rings **A**, **B**, and **C** up and down the Ni(II) coordination plane. Second, the phenyl group of the ring **B** is positioned underneath of the amino acid bearing ring **C** forcing the R substituent to be pointed in the opposite direction, avoiding any repulsive stereochemical interactions. One might agree that this type of indirect asymmetric induction is rather distinctive to these Ni(II) complexes.

Figure 5. Mechanistic rationale for the observed stereochemical outcome in the DTR and *S*/*R*-interconversion methods.

Conclusions

In summary, we have developed an advanced purely chemical DTR and *S/R*-interconversion methods for preparation of tailor-made, unnatural α -AAs using novel axially chiral ligands (*S*)- and (*R*)-17. These approaches can be used starting directly from unprotected α -AAs. All reactions can be conducted under operationally convenient conditions with good-to-excellent chemical yields and stereoselectivity (up to > 99:1). These methods show broad structural generality as demonstrated on 35 examples including various α -benzyl-, α -alkyl-, α -alkenyl, and α -heteroaryl-containing tailor-made α -AAs. The source of chirality in the presented methods, specially designed chiral and non-racemizable ligands (*S*)-17 and (*R*)-17, can be virtually completely recycled and reused for continuous production of the target enantiomerically pure α -AAs. Overall, the operational ease of the ACS Paragon Plus Environment

presented methods coupled with structural generality and attractive stereochemical outcome bode well for their widespread practical applications.

Experimental Section

General Information. The chemicals were purchased from commercial sources and used without further purification. Analytical thin layer chromatography (TLC) was performed on HSGF 254 (0.15–0.2 mm thickness). All products were characterized by NMR and MS spectra. ¹H and ¹³C NMR spectra were recorded in deuterochloroform (CDCl₃), dimethyl sulfoxide-*d*₆ (DMSO-*d*₆) or deuterium oxide (D₂O) on 400 or 500 MHz instrument. Chemical shifts were reported in parts per million (ppm, δ) downfield from tetramethylsilane. Proton coupling patterns were described as singlet (s), doublet (d), triplet (t), quartet (q), quintet (p), doublet of triplets (dt) and multiplet (m). High-resolution mass spectra (HRMS) was measured on Q-TOF spectrometer. The determination of dr was performed *via* LC/MS analysis. The determination of ee was performed *via* HPLC analysis or UFLC analysis. Optical rotations were measured using a 1 mL cell with a 10 mm path length on matic polarimeter and were reported as follows: [α] ²⁵ _D (c: g/100 mL, in solvent). Melting points were measured on melting point apparatus. All physicochemical data reported for the Ni(II) complexes are due to the single diastereomer after purification by chromatography or crystallization.

General Procedure.

General Procedure for the Synthesis of $(R_a)(S_c)$ -23a. To a suspension of (R)-17 (100 mg, 0.176 mmol, 1 equiv), *rac*-6-Cl-tryptophan 22a or (R)-6-Cl-tryptophan 22a (46 mg, 0.194 mmol, 1.1 equiv), Ni(OAc)₂·4H₂O (48 mg, 0.194 mmol, 1.1 equiv), K₂CO₃ (146 mg, 1.06 mmol, 6 equiv) were refluxed in methanol (6 mL) at 70 °C for 2 hrs. After cooling, the mixture was diluted with icy 2.5% aqueous acetic acid (25 mL), then extracted three times with dichloromethane. The combined organic layers were dried with Na₂SO₄, and concentrated *in vacuo*. The crude reaction mixture was

The Journal of Organic Chemistry

subjected to column chromatography on silica gel. Eluent PE: EA = 4:1 was used to remove the residual ligand (*R*)-17, followed by using eluent DCM: MeOH = 20:1 to obtain the mixture of the two diastereomers (R_a)(S_c)-23a and (R_a)(R_c)-23a (144 mg, yield 97%) for analysis (dr = 99:1). The mixture was purified again by column chromatography on silica gel (DCM: MeOH = 80:1) to give the major pure diastereomer (R_a)(S_c)-23a as a red solid.

Large-scale Preparation of $(S_a)(R_c)$ -23w.

To a suspension of (*R*)-**17** (10.0 g, 17.6 mmol, 1 equiv), *rac*-cyclohexylalanine **22w** (3.3 g, 19.4 mmol, 1.1 equiv), Ni(OAc)₂'4H₂O (4.8 g, 19.4 mmol, 1.1 equiv), K₂CO₃ (14.6 g, 106 mmol, 6 equiv) were refluxed in methanol (100 mL) at 70 °C for 12 hrs. After cooling, the mixture was concentrated *in vacuo*, then the residue was dissolved in dichloromethane, diluted with icy 2.5% aqueous acetic acid (500 mL), and extracted three times with dichloromethane. The combined organic layers were dried with Na₂SO₄, and concentrated *in vacuo*, then purified by column chromatography on silica gel to give the crude products (R_a)(S_c)-**23w** and (R_a)(R_c)-**23w** (13.3 g, yield 97%) for analysis (dr > 99:1). The crude products were purified again by recrystallization in ethanol to give the major pure diastereomer (R_a)(S_c)-**23w** as a red solid (12.9g, yield 94%).

General Procedure for the Synthesis of (*R*)-22j. To a suspension of $(S_a)(R_c)$ -23j (500 mg, 0.621 mmol, 1 equiv) in methanol (15 ml) was added 6 *N* HCl, and the whole was heated at 40 °C for 6 hrs. The reaction mixture was concentrated to dryness upon disappearance of the red color of the starting complex. The residue was added ethyl acetate (20 mL) and water (5 mL), stirred and separated. The organic phase was extracted sequentially with 1 *N* HCl (4 mL) and water (4 mL). The resulting organic phase was washed with saturated sodium hydrogen carbonate solution (5 mL), water (5 mL) and brine (5 mL), dried with Na₂SO₄, and concentrated to afford the recovered (*S*)-**17** (341 mg, yield 97%). The combined aqueous phase was evaporated *in vacuo* to the residue, which was dissolved in methanol (4 ml) and separated by preparative performance liquid chromatography using Agilent

1200 Series spectrometer with Eclipse XDB-C18 column (9.4×250 mm, 5μ m) (MeOH/H₂O = 5/95,

 λ = 214 nm, 5.0 mL/min) to afford pure (*R*)-**22j** as a white solid (118 mg, yield 95%).

General Procedure for the Synthesis of (*R*)-22y. To a suspension of $(S_a)(R_c)$ -23y (500 mg, 0.621 mmol, 1 equiv) in methanol (15 ml) was added 6 *N* HCl, and the whole was heated at 40 °C for 8 hrs. The reaction mixture was concentrated to dryness upon disappearance of the red color of the starting complex. The residue was added ethyl acetate (20 mL) and water (5 mL), stirred and separated. The organic phase was extracted sequentially with 1 *N* HCl (4 mL) and water (4 mL). The resulting organic phase was washed with saturated sodium hydrogen carbonate solution (5 mL), water (5 mL) and brine (5 mL), dried with Na₂SO₄, and concentrated to afford the recovered (*S*)-17 (373 mg, yield 97%). The combined aqueous phase was evaporated *in vacuo* to the residue, which was re-dissolved in a minimum amount deionized water and loaded on a Dowex 50×2 100 ion-exchange column. Washed with deionized water until neutral, the column was then washed with 10% aq. NH₄OH. The first fraction (400 mL) was collected and evaporated under vacuum to afford (*R*)-22y as a white solid (82mg, yield 93%).

General Procedure for the Synthesis of (*R*)-24y. *N*-benzyloxycarbonyloxysuccinimide (114 mg, 0.457 mmol, 1 equiv) was dissolved in 1 ml acetone at 0 °C, which was added a solution of (*R*)-22y (60 mg, 0.457 mmol, 1 equiv), sodium hydrogen carbonate (77 mg, 0.914 mmol, 2 equiv) and sodium carbonate (49 mg, 0.457 mmol, 1 equiv) in water (3 ml) and acetone (1 ml). The whole was stirred at room temperature for 12 hrs, then concentrated to remove the acetone. The residual aqueous phase was acidified with 1 *N* HCl to pH 4, and then white solid was precipitated out. The solid was collected by filtration to afford (*R*)-24y (109 mg, yield 90%, ee > 99%).

(*R*)-4-Chlorophenylalanine 22j: white solid (118 mg, yield 95%). mp 238.2–238.9 °C. [α]²⁵_D = -+29.0 (c 0.048, MeOH). ¹H NMR (400 MHz, D₂O) δ 7.28 (d, *J* = 8.1 Hz, 2H), 7.15 (d, *J* = 8.0 Hz, 2H), 3.85 (t, *J* = 6.4 Hz, 1H), 3.12 (dd, *J* = 14.5, 5.1 Hz, 1H), 2.98 (dd, *J* = 14.6, 7.9 Hz, 1H). ¹³C NMR (100 MHz, D₂O) δ 170.7, 132.9, 132.2, 130.7, 128.8, 53.5, 34.6. HRMS (ESI) *m/z*: calcd for C₉H₁₀CINO₂Na⁺ [M + Na]⁺: 222.0292, found: 222 .0292. The ee was determined by HPLC with an Astec CHIROBIOTICTM T chiral HPLC column (4.6 mm × 25 cm, 5 µm) (MeOH/H₂O = 90/10, λ =

The Journal of Organic Chemistry

214 nm, 0.5 mL/min). t_R (major enantiomer) = 21.173 min, t_R (minor enantiomer) = not found, ee > 99%.

(*R*)-*n*-Butylglycine 22y: white solid (82 mg, yield 93%). mp >300 °C. $[\alpha]^{25}_{D} = -29.0$ (c 0.056, MeOH). ¹H NMR (400 MHz, D₂O) δ 3.80 (t, *J* = 6.2 Hz, 1H), 1.88 – 1.71 (m, 3H), 1.32 – 1.19 (m, 4H), 0.78 (t, *J* = 6.9 Hz, 3H). ¹³C NMR (125 MHz, D₂O) δ 173.6, 53.8, 29.7, 26.2, 21.6, 12.9. HRMS (ESI) *m/z*: calcd for C₆H₁₄NO₂⁺ [M + H]⁺: 132.1019, found: 132.1018.

(*R*)-*c*-Butylglycine 22bb: white solid (86 mg, yield 96%). mp >300 °C. $[\alpha]^{25}_{D} = -39.6$ (c 0.048, MeOH). ¹H NMR (400 MHz, D₂O) δ 3.87 (d, *J* = 9.1 Hz, 1H), 2.67 (h, *J* = 9.3 Hz, 1H), 2.06 – 1.63 (m, 6H).. ¹³C NMR (125 MHz, D₂O) δ 171.5, 56.7, 35.2, 25.0, 24.8, 17.3. HRMS (ESI) *m/z*: calcd for C₆H₁₂NO₂⁺ [M + H]⁺: 130.0863, found: 130.0862.

(S)-3-(2-Thienyl)alanine 22hh: white solid (106 mg, yield 96%). mp 222.4–224.0 °C. $[\alpha]^{25}_{D} = -8.3$ (c 0.048, MeOH). ¹H NMR (400 MHz, D₂O) δ 7.28 (d, J = 4.8 Hz, 1H), 6.96 – 6.89 (m, 2H), 4.19 (t, J = 5.7 Hz, 1H), 3.54 – 3.20 (m, 2H). ¹³C NMR (125 MHz, D₂O) δ 171.5, 135.2, 128.2, 127.7, 126.3, 54.3, 29.7. HRMS (ESI) *m/z*: calcd for C₇H₁₀NO₂S⁺ [M + H]⁺: 172.0427, found: 172.0427. The ee was determined by HPLC with an Astec CHIROBIOTICTM T chiral HPLC column (4.6 mm × 25 cm, 5 µm) (MeOH/H₂O = 80/20, λ = 214 nm, 1.0 mL/min). t_R (major enantiomer) = 6.174 min, t_R (minor enantiomer) = not found, ee > 99%.

(*R*)-*N*-Cbz-*n*-Butylglycine 24y: white solid (109 mg, yield 90%). mp 54.2–54.8 °C. $[\alpha]^{25}_{D}$ = +7.1 (c 0.056, MeOH). ¹H NMR (400 MHz, DMSO-*d*₆) δ 12.54 (s, 1H), 7.57 (d, J = 8.0 Hz, 1H), 7.42 – 7.20 (m, 5H), 5.03 (s, 2H), 3.91 (td, J = 9.1, 4.8 Hz, 1H), 1.74 – 1.49 (m, 2H), 1.33 – 1.22 (m, 4H), 0.85 (t, J = 6.9 Hz, 3H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ 174.5, 156.6, 137.5, 128.8, 128.2, 128.2, 65.8, 54.2, 30.9, 28.2, 22.1, 14.2. HRMS (ESI) *m/z*: calcd for C₁₄H₂₀NO₄⁺ [M + H]⁺: 266.1392, found: 266.1381. The ee was determined by UFLC with a Chiralpak AD-H column (4.6 mm × 25 cm) (*n*-hexane + 0.1% TFA/*i*-PrOH = 90/10, λ = 214 nm, 1.0 mL/min). t_R (major enantiomer) = 31.147

min, t_R (minor enantiomer) = not found, ee > 99%.

(*R*)-*N*-Cbz-*c*-Butylglycine 24bb: white solid (111 mg, yield 91%). mp 106.4–107.2 °C. $[\alpha]^{25}_{D} = -6.5$ (c 0.062, MeOH). ¹H NMR (400 MHz, DMSO-*d*₆) δ 12.48 (s, 1H), 7.55 (d, *J* = 7.9 Hz, 1H), 7.41 – 7.24 (m, 5H), 5.03 (s, 2H), 3.91 (t, *J* = 8.5 Hz, 1H), 2.67 – 2.50 (m, 1H), 2.03 – 1.59 (m, 6H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ 173.4, 156.7, 137.5, 128.8, 128.3, 128.2, 65.9, 58.7, 36.6, 25.5, 25.3, 17.9. HRMS (ESI) *m/z*: calcd for C₁₄H₁₈NO₄⁺ [M + H]⁺: 264.1236, found: 264.1225. The ee was determined by UFLC with a Chiralpak AD-H column (4.6 mm × 25 cm) (*n*-hexane + 0.1% TFA/*i*-PrOH = 85/15, λ = 214 nm, 1.0 mL/min). t_R (major enantiomer) = 21.294 min, t_R (minor enantiomer) = 14.294, ee > 99%.
