Received July 21, 1997[®]

A rapid and efficient synthetic procedure has been developed to prepare new ferrocene derivatives such as β -ferrocenylvinyl heterocumulenes and ferrocene-containing imidazole ring bearing one, two, or three ferrocene subunits. The method is based on the aza Wittig reaction of $[(\beta-\text{ferrocenylvinyl})\text{imino}]$ phosphorane **3**, readily available from ferrocenecarboxaldehyde by sequential treatment with ethyl azidoacetate and triphenylphosphine, with isocyanates and further treatment with the appropriate primary amine. The crystal structures of compounds 6c (monoferrocene derivative), 11c, and 12b (biferrocene derivatives) have been determined by single-crystal X-ray methods. The electrochemical properties of these new compounds are also reported.

Considerable attention has been paid in the last few years to supramolecular systems containing a ferrocene unit and a fragment able to act as ligand, with a welldefined geometry because of its fixed intramolecular spacing, toward transition-metal ions; these systems can behave either as chemical sensors¹ or as redox-active and photoactive molecular devices.² In addition, supramolecular systems containing more than one metallocene unit have attracted a great deal of attention.³ In particular, bridging two or three ferrocene subunits generates redox systems which have been the subject of recent studies due to their great potential as partially oxidized species exhibiting mixed-valence behavior or electronic delocalization⁴ and as models for poly(ferrocenyl)silane materials.⁵ On the other hand, the ferrocene subunit has been incorporated into more complex structures, which then displayed a high degree of nonlinear optical (NLO) behavior, liquid crystalline, ferromagnetic, or catalytic properties.⁶

The present work was undertaken to synthesize and characterize a range of ferrocene-containing species with P- or sp/sp²/sp³/N-donor groups which may be able to act as ligand toward transition-metal ions. To our knowledge, no ferrocenylimidazole derivatives have been described, in spite of the fact that ferrocenylsubstituted pyrazoles⁷ and many ferrocenyl-substituted pyridines⁸ have been studied, especially in the context of the design of redox spectators.

Results and Discussion

We chose to use the $[(\beta-\text{ferrocenylvinyl})\text{imino}]$ phosphorane 3 as a building block for the synthesis of the new ferrocene derivatives. Ferrocenecarboxaldehyde (1) underwent Knoevenagel condensation with ethyl azidoacetate in the presence of NaEtO at -15 °C to give the β -ferrocenylvinyl azide **2** in 82% yield. Staudinger reaction of azide 2 with triphenylphosphine in dry dichloromethane at room temperature provided the key intermediate, iminophosphorane 3, in 93% yield. The ¹H NMR spectrum of **3** is characteristic: the ferrocenyl substituent gives rise to a five-proton singlet at 4.04 ppm for the unsubstituted cyclopentadienyl ring and two apparent triplets at 4.17 and 4.87 ppm, respectively, corresponding to the AA'MM' pattern for the monosub-

stituted ring. Similar behavior was observed in the $^{13}\mathrm{C}$ NMR spectrum.

It is important to note that the iminophosphorane moiety possesses a high complex-forming capacity with a wide variety of metal compounds⁹ and metal carbonyls,¹⁰ so **3** could be of valuable interest for the preparation of redox-functionalized metal complexes.

(Vinylimino)phosphorane **3** was converted in a oneflask reaction into the corresponding highly functionalized ferrocenylimidazole **6** in yields higher than 70%. This conversion involves aza Wittig reaction with benzyl or alkyl isocyanates at room temperature and further treatment of the resulting carbodiimide **4** with aliphatic or aromatic primary amines to give ferrocenylguanidines **5** as intermediates, which undergo cyclization at room temperature to give **6**. Compound **3** also reacted with aromatic isocyanates to give the expected carbodiimide **7**, which by reaction with aliphatic amines provided **6** but did not react with aromatic amines at room temperature. At higher temperatures, complex mixtures

160 °C, a mixture of isocyanate **9** (70%) and the bis(β -ferrocenylvinyl)carbodiimide **10** (20%) was obtained. The latter compound can be obtained in 95% yield by intermolecular aza Wittig reaction of the (vinylimino)-phosphorane **3** and the vinyl isocyanate **9** in toluene at reflux temperature (Scheme 2). The ¹H and ¹³C NMR spectra of **10** revealed that the two ferrocene subunits are equivalent. Compound **10**, whose structure has been determined by X-ray analysis,¹¹ represents a novel example of biferrocene compounds in which the bridging unit is an unsaturated carbodiimide.

The present approach to ferrocenylimidazoles enables the design of novel complex ferrocene-containing heterocycles bearing two or three ferrocene subunits. Thus, carbodiimide **10** reacted with α -unsubstituted primary amines in dry dichloromethane at room temperature to give bis(ferrocenyl)imidazole derivatives **11** in yields ranging from 83% to 95% (Table 1, Scheme 3). The ¹H and ¹³C NMR spectra of compounds **11** showed two sets of signals for the two ferrocene subunits, indicating that they are nonequivalent. Namely, in the ¹³C NMR spectra of **11**, only three resonances are observed for each substituted Cp ring (and one resonance for each unsubstituted ring), implying that the Cp rings undergo rapid rotation. The reaction of **10** with isopropylamine

under the same conditions afforded two compounds. The major product (62%) was found to be 11d, whose spectroscopic properties are nearly identical to those of **11a-c**. The minor product **12a** (26%) has the same microanalytical data; however, the ¹H and ¹³C NMR spectra showed striking differences with respect to those of 11d. The ¹³C NMR spectrum not only showed separate sets of signals for the two ferrocene subunits, as in 11, but also showed five separate resonances for each substituted Cp ring, thus indicating the lack of any symmetry element relating to them.¹² When **10** was treated with *tert*-butylamine at room temperature, starting material was recovered unaltered; however, when the reaction was carried out at 100 °C, 12b was isolated as the only reaction product in 40% yield. The spectroscopic properties of 12b are nearly identical to those of **12a**. The behavior of carbodiimide **10** toward primary amines can be rationalized by initial formation of a guanidine derivative which undergoes cyclization across either the alkylamino group or the (β -ferroce-

Scheme 3

nylvinyl)amino group, depending on the degree of substitution on the carbon atom adjacent to the amino group.

In order to identify unambiguously the proposed structures, X-ray structure determination of **11** and **12** was performed. The structures **11c** (Figure 2, Table 3) and **12b** (Figure 3, Table 4) reveal that the two ferrocene subunits are orthogonal (Cp11–Cp31 = 86.8° for **11c**, and Cp11–Cp31 = 87.2° for **12b**) with respect to each other, and the intramolecular Fe–Fe separation is almost the same (9.572 Å) for both compounds. A final point is concerned with the conformation of the cyclopentadienyl ring in each subunit. The conformation is, in both subunits, almost eclipsed. It has been pointed out that the energy difference between the two conformers is rather small,¹³ and the stability order may be altered through the introduction of substituents on the cyclopentadienyl ring(s).

Carbodiimide **10** also reacted with ferrocenylmethylamine¹⁴ in dichloromethane at room temperature to give the tris(ferrocenyl) compound **13** in 60% yield. The

¹³C NMR spectrum showed three sets of signals for the three ferrocene subunits (Scheme 4).

The cyclic voltammograms of **6a**-**c** (Figure 4) show that the ratio of the current intensity of the anodic peak over the intensity of the cathodic peak (i_{pa}/i_{pc}) was approximatly equal to 1 over the potential scan rate range 0.01–0.2 V s⁻¹, and the peak-to-peak separation was 65–67 mV. Under the same experimental conditions, the one-electron oxidation of ferrocene itself displays an E_p of 64 mV, thus indicating that departure from the constant value of 59 mV expected for an

^a Peak-to-peak separation measured at 100 mV s⁻¹.

they show the electron-donating abilities of the substituents, which makes the electron removal about 32-53 mV easier when compared with that of ferrocene.

Biferrocene derivatives 10 and 11c exhibit cyclic voltammograms characteristic of superimposed oneelectron waves,¹⁶ with a peak-to-peak separation notably higher than the 57 mV expected for a two-electron process involving non-interacting centers.¹⁷ The values of $E_{1/2}(1)$ and $E_{1/2}(2)$ were estimated by using the method outlined by Richarson and Taube.¹⁸ The difference $(E_{1/2})$ between the first and second half-wave potentials gives values of K_c significantly higher than the statitiscal value for 4, which reveals a small but significant electronic interaction between the two redox centers through the organic chain attached to the ferrocenyl subunits.

The cyclic voltammogram of derivative 13 (Figure 4) shows one oxidation wave at $E_{pa} = 0.603$ V vs SCE, which implies that only very weak interactions between the ferrocenyl subunits are presented.

In conclusion, the aza Wittig reaction, which has not been used before in ferrocene chemistry, appears to be a simple but very effective new way to prepare a wide variety of ferrocene derivatives, in which the ferrocene group is conjugated either to a heterocumulene fragment or to a highly functionalized imidazole ring. The method also works for the preparation of bi- and triferrocene derivatives. These relatively complex and unreported structures are prepared under mild reaction conditions, with high yields, and from the readily available starting material [$(\beta$ -ferrocenylvinyl)imino]phosphorane 3.

Experimental Section

General Methods. General experimental conditions and spectroscopic instrumentation used have been described.¹⁹

The cyclic voltammetric measurements were performed with a QUICELTRON potentiostat/galvanostat, controlled by a personal computer and driven by dedicated software. Experiments were carried out in a three-electrode cell. The counter electrode was platinum foil, and the reference was a saturated calomel electrode (SCE). The cyclic voltammetry was performed at a platinum disk working electrode with a variable scan rate.

First, 5 mL of CH₂Cl₂/CH₃CN (1:1) solution containing 0.1 M [nBu₄N][ClO₄] was poured into the cell, followed by 5 mmol of the derivative (10^{-3} M) . The same electrodes were used for cyclic voltammetry performed in DMF. Deoxygenation of the

^{*a*} $R1 = \sigma ||F_0| - |F_c||/\sigma |F_0|$ for reflections with $I > 2\sigma I$. ^{*b*} $wR2 = [\sigma[w(F_0^2 - F_c^2)^2]/\sigma[w(F_0^2)^2]]^{0.5}$ for all reflections; $w^{-1} = \sigma^2(F^2) + (aP)^2 + bP$, where $P = (2F_c^2 + F_0^2)/3$, and *a* and *b* are constants set by the program.

solutions was achieved by bubbling nitrogen for at least 10 min. All of the potential values are referred to SCE.

X-ray Crystallography. Crystals obtained by liquid diffusion from CH₂Cl₂/Et₂O (6c), CH₂Cl₂/iPr₂O (11c), and CH₃-COOEt/n-hexane (12b· $1/_2Et_2O$) were respectively mounted in inert oil on a glass fiber and transferred to the diffractomer (Siemens P4 with LT2 low-temperature attachment), as summarized in Table 6. The data were collected at 173 K using graphite monochromated Mo Ka radiation (0.710 73 Å) according to the ω -scans method in the region $6.2 \le 2\theta \le 50.0^{\circ}$. Unit cell parameters were determined from a least-squares fit of 72 (6c), 42 (11c), and 74 (12b·1/2Et2O) accurately centered reflections (9 < 2θ < 25°). An absorption correction based on φ -scans was applied, with transmision factors 0.74–0.99 (6c), 0.74-0.76 (**11c**), and 0.74-0.95 (**12b**· $\frac{1}{2}Et_2O$). The structures were solved by direct methods and refined on F^2 by means of the full-matrix least-squares method. The N-H hydrogen atom was found in the final Fourier F map and refined as a free variable for all three compounds. Other hydrogen atoms were included using a riding model, except for those of the methyl groups of 6c, which were refined as rigid. The programs use the neutral atom scattering factors, $\Delta f'$ and $\Delta f''$, and absorption coefficients.20

Preparation of α-Azido-β-ferrocenylpropenoic Acid Ethyl Ester (2). A mixture of ethyl azidoacetate (4.82 g, 37.2 mmol) and ferrocenecarboxaldehyde (1, 2.00 g, 9.3 mmol) was added dropwise under nitrogen at -15 °C to a well-stirred solution containing sodium (0.86 g, 37.2 mmol) in 25 mL of anhydrous THF. The reaction mixture was stirred at that temperature for 7 h and then allowed to warm to room temperature. The resultant solution was poured into aqueous 30% ammonium chloride (50 mL) and then extracted with diethyl ether (3 × 50 mL). The combined organic layers were washed with water (3 × 50 mL), dried over anhydrous magnesium sulfate, and filtered. Concentration to dryness yielded a crude material, which was chromatographed on a silica gel column using ethyl acetate/*n*-hexane (1:3) as eluent to give **2** in 82% yield, which was recrystallized form diethyl ether/*n*-hexane (1:1): mp 84–86 °C, red prisms; ¹H NMR (CDCl₃) δ 1.39 (t, 3H, J = 7.1 Hz), 4.15 (s, 5H), 4.33 (q, 2H, J = 7.2 Hz), 4.40 (t, 2H, J = 1.7 Hz), 4.47 (t, 2H, J = 1.7 Hz), 6.78 (s, 1H); ¹³C NMR (CDCl₃) δ 14.3, 61.9, 69.6, 70.8, 70.7, 122.5, 127.6, 163.5; EI-MS *m*/*z* (relative intensity) 325 (M⁺, 8), 224 (100), 121 (54). Anal. Calcd for C₁₅H₁₅N₃O₂Fe: C, 55.41; H, 4.65; N, 12.99. Found: C, 55.54; H, 4.76; N, 13.34.

Preparation of β **-Ferrocenvl-** α **-[(Triphenvlphospho**ranylidene)amino]propenoic Acid Ethyl Ester (3). To a solution of 2 (0.25 g, 0.8 mmol) cooled at 0 °C in anhydrous dichloromethane (10 mL) was added a solution of Ph₃P (0.22 g, 0.9 mmol) in the same solvent (5 mL) dropwise under nitrogen. The resultant mixture was then allowed to warm at room temperature and stirred for 24 h. The solvent was removed under reduced pressure, and the crude solid was chromatographed on a silica gel column using ethyl acetate/ n-hexane (1:3) as eluent to give 3 in 93% yield, which was recrystallized from dichloromethane/diethyl ether/n-hexane (1:2:1): mp 142–144 °C, red prisms; ¹H NMR (CDCl₃) δ 0.97 (t, 3H, J = 7.1 Hz), 3.82 (q, 2H, J = 7.2 Hz), 4.04 (s, 5H), 4.17 (t, 2H, J = 1.8 Hz), 4.87 (t, 2H, J = 1.7 Hz), 6.52 (d, 1H, ${}^{4}J_{PH}$ = 6.3 Hz), 7.39–7.45 (m, 9H) 7.76 (ddd, 6H, ${}^{3}J_{PH} = 12$, ${}^{3}J =$ 7.8, and ${}^{4}J$ = 1.6 Hz); ${}^{13}C$ NMR (CDCl₃) δ 14.1, 60.4, 68.3, 68.9, 69.7, 82.9, 117.0 (d, ${}^{3}J_{PC} = 20.6$ Hz), 128.1 (d, ${}^{3}J_{PC} = 20.6$ Hz), 130.8 (d, ${}^{4}J_{PC} = 20.6$ Hz), 132.4 (d, ${}^{2}J_{PC} = 9.6$ Hz), 133.5 (d, ${}^{1}J_{\rm PC}$ = 102.7 Hz), 134.1 (d, ${}^{2}J_{\rm PC}$ = 7.1 Hz), 167.7 (d, ${}^{3}J_{\rm PC}$ = 20.6 Hz); ³¹P NMR (CDCl₃) δ 4.9; EI-MS m/z (relative intensity) 559 (M⁺, 100), 226 (16), 183 (59), 121 (57). Anal. Calcd for C₃₃H₃₀NO₂PFe: C, 70.85; H, 5.41; N, 2.51. Found: C, 70.61; H, 5.59; N, 2.29.

General Procedure for the Preparation of Ferrocenylimidazoles 6. To a solution of iminophosphorane **3** (0.25 g, 0.5 mmol) in anhydrous dichloromethane (15 mL) was added the appropriate isocyanate (0.5 mmol) in the same solvent (5 mL). The resultant reaction mixture was stirred at room
