## Summary

When the Hammett-Taft equation $\log \left(k / k_{\mathrm{o}}\right)=\rho^{q} \cdot \sigma_{1}^{q}$ is applied to the solvolysis of the 3 -substituted propyl bromides $\mathbf{6 a - 6 i}$ in ethanol/water 4:1 ( $\nu / v) \log k$ correlates linearly with $\sigma_{1}^{q}$ except in cases where R exerts an anchimeric effect. The reaction constant $p^{q}$ for 6 is -0.12 and is typical for a nucleophilic solvent-assisted $k_{\mathrm{s}}$ process at a primary C -atom. The tertiary halides $\mathbf{1}$ and $\mathbf{3}$, however, which react with little or no nucleophilic solvent assistance, i.e. by $k_{\mathrm{c}}$ processes, lead to larger $\rho^{q}$ values of -0.71 and -1.14 , respectively. The reaction constant $\rho^{q}$ is therefore a sensitive gauge for charge development in the transition state for solvolysis of saturated compounds.

Introduction. - As recently reported [1] the solvolysis rates of the tertiary chlorides 1 in ethanol/water 4: $1(v / v)$ fit the Hammett-Taft equation (1) only if $R$ in $\mathbf{1}$ is a neutral

$$
\begin{equation*}
\log \left(k / k_{\mathrm{o}}\right)=\rho^{\mathrm{q}} \cdot \sigma_{1}^{\mathrm{q}} \tag{1}
\end{equation*}
$$

or electron withdrawing substituent, such as $\mathrm{H}, \mathrm{CH}_{3},\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NCH}_{2}, \mathrm{ClCH}_{2}, \mathrm{Cl}, \mathrm{CN}$ or $\mathrm{NO}_{2}$. The value of $\sigma_{1}^{q}$ in equation (1) is the inductive substituent constant of R derived from the $\mathrm{p} K_{\mathrm{a}}$ of 4 -R-substituted quinuclidinium perchlorates 2 [2]. The linear relationship between $\log k$ for 1 and $\sigma_{1}^{q}$ shows that the substituents control the rates of these tertiary chlorides by their inductive effect only ${ }^{2}$ ). The reaction constant $\rho^{\mathrm{q}}$, a measure of the sensitivity of the rate to the nature of $\mathbf{R}$, was -0.71 . Consequently, a $\rho$ value of this magnitude was considered to be characteristic for the solvolysis of acyclic tertiary halides, which were hitherto thought to ionize without nucleophilic solvent assistance and were therefore classified as $k_{\mathrm{c}}$ processes [5] [6].

Recently, however, Bentley et al. [7] have adduced evidence for significant assistance by the more nucleophilic solvents in the solvolysis of $t$-butyl bromide,

[^0]which therefore shows some $k_{\mathrm{s}}{ }^{3}$ ) character [5] [6] ${ }^{4}$ ). On the other hand, solvolyses of 1-bromoadamantanes ( $\mathbf{3}, \mathrm{R}=\mathrm{H}$ ), in which rearside attack by solvent is excluded, must be considered true $k_{\mathrm{c}}$ processes.

A gradual increase in nucleophilic solvent participation in going from a $k_{c}$ - to a $k_{s}$-process should be reflected in a decrease in the size of the reaction constant $\rho^{q}$ (equation 1) because the amount of positive charge developed at $C(a)$ in the transition state diminishes. Thus, in the transition state $\mathbf{4}$ for the ionization of $\mathbf{3}$ the positive charge is transferred to the incipient adamantyl cation, whereas in the transition state for 1 part of the charge is transferred to the solvent SOH , as illustrated in 5 . This is borne out by the observed $\rho^{\mathrm{q}}$ values for 3 and $\mathbf{1}$, which are -1.14 [3] and -0.71 [1], respectively.

It was therefore of interest to determine the $p^{q}$ value for primary halides, such as the 3 -substituted propyl bromides $\mathbf{6 a - i}$, since they should react by solvent displacement, i.e. by a true $S_{N} 2$ or $k_{\mathrm{s}}$-process [6] [9] with little or no positive charge development at the primary C -atom in the transition state 7. Hence, electrostatic interaction with the substituent R is expected to be minimal and a low $\rho$ value should result.

These trends were in fact anticipated by Streitwieser [10] who applied equation (1) and Taft's $\sigma^{*}$ polar substituent constants to literature data on the solvolysis of primary, secondary and tertiary halides and sulfonates. However, in view of the paucity of data and the contradictory statements of Pritzkow \& Schöppler [11] ${ }^{5}$ ) a more detailed study of polar substituent effects in the solvolysis of primary halides seemed desirable. The bromides $\mathbf{6 a - i}$ were chosen in order to permit a comparison with their tertiary counterparts 1.

As also pointed out by Streitwieser [10] neighboring nucleophilic substituents $\mathbf{R}$ participate in the ionization and thus cause deviations from the expected linear correlation of $\log k$ with $\sigma_{1}^{q}$, which provide a reliable measure of Winstein's anchimeric effect ${ }^{6}$ ). However, R-participation was not anticipated in the case of $\mathbf{6 a - e}$, but did present a likely reaction pathway for $\mathbf{6 g}, \mathbf{6 h}$ and $\mathbf{6 i}$.

Results. - The rate constants for the bromides 6a-i (Table 1), which were measured conductometrically in ethanol/water $4: 1(v / v)$ obeyed the pseudo first order or first order rate law. Inclusion of a base, such as triethylamine, to neutralize the HBr generated in the reaction, is necessary because the acid tends to react with ethanol above $100^{\circ}$, causing a decrease in conductivity. However, addition of 1 to 3 mol-equiv. of triethylamine did not affect the rate constants at low concentrations of the bromides 6 , i.e. 0.001 m .

Preparative solvolyses of the bromides 6a-i were carried out in acetone/water 7:3(v/v), because ethanol interfered with the quantitative determination of volatile products and their identification by gas chromatography. Solutions of 6 of higher

concentration ( 0.05 m ) were reacted at $130^{\circ}$ in the presence of 0.055 m diisopropylamine, since triethylamine tended to react with 6 under these conditions. Reaction times (ca. 10 half lives) and products are listed in Table 2.

The bromides 6 a-f underwent hydrolysis to the corresponding primary alcohols, accompanied in some cases by small amounts of olefins. The bromoalcohols $\mathbf{6 g}$ yielded $25 \%$ of oxetane $\mathbf{8}$ beside 1,3-propanediol. Hydrolysis of the bromoester $\mathbf{6 h}$ yielded mostly ethyl 4-hydroxybutyrate 9 beside $\gamma$-butyrolactone $\mathbf{1 0}$, which appears

to be a secondary product, since its yield increased to $100 \%$ after a longer reaction time (Table 2). Compound 6i afforded only $N, N$-dimethylazetidinium bromide $11(\mathrm{X}=\mathrm{Br})$, which was isolated in quantitative yield as the Reineckate $11\left(\mathrm{X}=\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{SCN})_{4}\right)$.

Discussion. - In the Figure $\log k$ values for the bromides 6a-i are plotted against the corresponding $\sigma_{1}^{q}$ values listed in Table 3. The points for $6 \mathbf{a}-\mathrm{f}$ fit the regression line, whereas the points for $\mathrm{R}=\mathrm{OH}(\mathbf{6 g}), \mathrm{COOC}_{2} \mathrm{H}_{5}(\mathbf{6 h})$ and $\mathrm{N}\left(\mathrm{CH}_{3}\right)_{2}(\mathbf{6 i})$ deviate significantly. These deviations correspond to rate accelerations of $1.6,5.2$ and $9.4 \cdot 10^{3}$, respectively, and must be attributed partly or wholly to neighboring group participation ${ }^{7}$ ). In support of this kinetic evidence 6 g yields $25 \%$ of oxetane by partic-

ipation of the O -atom at $\mathrm{C}(3)$, whereas the ester 6 h evidently reacts by participation of the O -atom at $\mathrm{C}(4)$ to furnish the intermediate 12 , which adds water to the cyclic ortho-diester 13, the precursor of the hydroxyester 9 and the $\gamma$-lactone 10. Prolonged heating converts the former quantitatively to the lactone $\mathbf{1 0}$ (Table 2). The dimethylamino group in $6 \mathbf{i}$ exerts the largest anchimeric acceleration of $c a .10^{4}$, which is in good agreement with our earlier findings for the corresponding chloride ( $\mathbf{6 i}, \mathrm{Cl}$ for $\mathrm{Br})$ [13].

The reaction constant $\rho^{q}$ derived from the slope of the regression line (Fig.) for the primary bromides $6 \mathbf{a}-\mathbf{f}$ is -0.12 . This value is $c a$. six times and ten times, respectively, smaller than the $\rho^{q}$ values observed for the tertiary chlorides 1 and the adamantyl bromides 3 and confirms the small effect of polar substituents on the solvolysis rates of primary reactants. These variations of $\rho$ values substantiate their usefulness as a tool for gauging charge development at the reaction site in the transition state. However, as shown elsewhere [14] other factors beside nucleophilic

Fig. Plot of $\log \mathrm{k}$ for $6 \mathrm{a}-\mathrm{i}$ in ethanol/water $4: 1(\mathrm{v} / \mathrm{v}) \mathrm{vs}$. inductive substituent constants for $R$
solvent participation contribute to the magnitude of $\rho$ in solvolytic reactions of compounds of the type $\mathrm{R}-\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{X}$.

It is instructive to compare $\rho$ values based on $\sigma_{I}^{\mathrm{q}}$ constants with those based on Taft's $\sigma_{1}$ constants [15]. A plot of $\log k$ for $\mathbf{6 a - f}$ against the latter constants leads to a $\rho$ value of -0.60 , which is numerically five times as large as our $\rho^{\text {q }}$ value of -0.12 . This difference is due to the different models from which the substituent constants $\sigma_{\mathrm{I}}$ (Taft) and $\sigma_{\mathrm{I}}^{\mathrm{q}}$ are derived $[2 \mathrm{a}]^{8}$ ). In fact they are related by the equation $\sigma_{\mathrm{I}}=0.200 \cdot \sigma_{\mathrm{I}}^{\mathrm{q}}-0.07$.

This work was supported by the 'Schweizerischer Nationalfonds zur Förderung der wissenschaftlichen Forschung', grant Nr. 2.819.0.77.

## Experimental Part

Melting points (m.p.) were determined on a Kofler-Block and are corrected ( $\pm 1^{\circ}$ ). If not stated otherwise, IR.- and ${ }^{1} \mathrm{H}-\mathrm{NMR}$.-spectra were in agreement with the indicated structures.

Syntheses. Most of the compounds 6 and their hydrolysis products are commercially available. The rest were prepared as follows:

Preparation of 3-bromo-1-dimethylaminopropane (6i) hydrobromide. A mixture of 51.5 g ( 0.5 mol ) 3-dimethylamino-1-propanol with 220 ml of $48 \%$ aqueous HBr -solution was prepared by cooling and then boiled under reflux. After each further hour $57,22,18,9,7$ and 4 ml of solvent were distilled off and after 3 further hours another 72 ml . The yellowish solution was cooled to $70^{\circ}, 300 \mathrm{ml}$ of acetone

[^3]were added and the mixture was cooled to $0^{\circ}$. The hygroscopic crystals, which were deposited after 12 h , were filtered off under argon and dried over $\mathrm{P}_{2} \mathrm{O}_{5}$. Yield $97.6 \mathrm{~g}(79 \%)$ of $6 \mathrm{i} \cdot \mathrm{HBr}$, m.p. $107-109^{\circ}$.

## $\mathrm{C}_{5} \mathrm{H}_{13} \mathrm{Br}_{2} \mathrm{~N}(246.98) \quad$ Calc. C $24.31 \quad \mathrm{H} 5.30 \quad \mathrm{~N} 5.67 \% \quad$ Found $\mathrm{C} 24.14 \quad \mathrm{H} 5.45 \mathrm{~N} 5.85 \%$

Preparation of 3-bromo-I-methoxypropane ( 6 f ). A suspension of 6.0 g ( 0.043 mol ) 3-bromo-1propanol and $8.43 \mathrm{~g}(0.057 \mathrm{~mol})$ trimethyloxonium tetrafluoroborate in $60 \mathrm{ml} \mathrm{CH}_{2} \mathrm{Cl}_{2}$ was heated under reflux. Then 20 ml water and solid $\mathrm{K}_{2} \mathrm{CO}_{3}$ were added carefully until the solution reacted alkaline. The organic layer was separated, washed once with sat. aqueous NaCl -solution and dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. Distillation through a Vigreux-column yielded 3.8 g ( $58 \%$ ) of colorless oil, b.p. $130-131^{\circ}$ (Lit. [17]: b.p. $129^{\circ}$ ).

Preparation of 3-methoxy-l-propanol. To $20.0 \mathrm{~g}(0.144 \mathrm{~mol})$ of 3-bromo-1-propanol in 20 ml of abs. methanol a solution of $6.62 \mathrm{~g}(0.288 \mathrm{~mol})$ sodium in 70 ml of abs. methanol was added with stirring at $20^{\circ}$ within 1 h . After 1 h of refluxing the solution was neutralized with 2 N HCl and extracted twice with ether. The combined extracts were dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and evaporated to dryness through a column. The oily residue was distilled in vacuo yielding $2.58 \mathrm{~g}(20 \%)$, b.p. $53^{\circ} / 14$ Torr (Lit. [18]: 149-150 $/ 760$ Torr).

3-Hydroxybutyronitril was prepared according to [19].
$\mathrm{N}, \mathrm{N}$-Dimethylazetidinium-reineckate (11, X $\left.=\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{NCS})_{4}\right)$ was obtained by reaction of $6 \mathbf{i}$ ethanol/water $4: 1(\mathrm{v} / \mathrm{v})$ and precipitation with ammonium reineckate according to an earlier procedure [20]. Violet platelets from acetone/water, m.p. $210^{\circ}$ (dec.); yield $100 \%$.

$$

Preparative solvolyses were carried out in acetone/water $7: 3(v / v)$ at the temperatures and for the periods of time indicated in Table 2. Samples of the reaction solutions were injected directly into the gas chromatography apparatus (Perkin-Elmer Model 3920) equipped with a $10 \%$ FFAP on chromosorb W-column. Retention times and relative yields were determined by calibration with authentic samples and with the aid of a Varian integrator CDS 111.

Rate measurements were carried out in ethanol/water $4: 1(v / v)$ with the conductance apparatus described previously [21].
