**Abstract** A simple and efficient method is reported for rapid chemoselective transformation of 1,1-diacetates to the parent aldehydes using 1,3-dibromo-5,5-dimethylhydantoin or N-bromosuccinimide in the presence of wet SiO<sub>2</sub> (50%, w/w) as solid support under solvent-free conditions at room temperature. This procedure has valuable advantages, for example short reaction times, simple workup, high yields of products, absence of solvent, and use of commercially available and non-toxic reagents.

**Keywords** 1,1-Diacetates · Aldehydes · Wet silica gel · 1,3-Dibromo-5,5-dimethylhydantoin · N-Bromosuccinimide · Solvent-free conditions

carbonyl groups have attracted special attention in protection and deprotection reactions by virtue of their high reactivity. One useful practice for protection of carbonyl groups is 1,1-diacetylization, which has received considerable interest in recent years, because 1,1-diacetates are stable in mildly acidic and basic media and are easily prepared [3–10]. However, the search for appropriate and efficient methods for deprotection of 1,1-diacetates to the corresponding carbonyl compounds is still in high demand. In this regard, much effort has been devoted to developing numerous methodologies using various reagents such as phosphorus trichloride [11], boron triiodide-N,N-diethylaniline complex [12], mineral solid supports [13],  $MoO_2(acac)_2$  [14],  $FeCl_3 \cdot 6H_2O$  [15], graphite [16], CuCl<sub>2</sub>·2H<sub>2</sub>O [17], zirconium sulfophenyl phosphonate [18], ceric ammonium nitrate (CAN) [19], indium trichloride [20], [NO<sup>+</sup>. crown. H (NO<sub>3</sub>)<sub>2</sub><sup>-</sup>] [21], Caro's acid/SiO<sub>2</sub> [22], H<sub>6</sub>P<sub>2</sub>W<sub>18</sub>O<sub>62</sub>·24H<sub>2</sub>O [23],  $Fe_2(SO_4)_3 \cdot xH_2O$  [24], 12-molybdophoshoric acid [25], p-toluene sulfonic acid [26],  $SO_4^{2-}/SnO_2$  [27], molybdenum tungsten polyoxometalates [28], KBrO<sub>3</sub>/MoO<sub>3</sub> [29], (NH<sub>4</sub>)<sub>3</sub>PW<sub>12</sub>O<sub>40</sub> [30], dodecatungstophosphoric acid (H<sub>3</sub>PW<sub>12</sub>O<sub>40</sub>) [31], sodium hydrogen sulfate in poly(ethylene glycol) [32], indium tribromide/[bmim]PF<sub>6</sub> [33], indium tribromide in poly(ethylene glycol) [34], 2,6-dicarboxypyridinium chlorochromate [35], and ZrOCl<sub>2</sub> [36]. Although many of these procedures have been satisfactorily used for this propose, most suffer from one or more drawbacks, for example low yields, harsh reaction conditions, difficult work-up, and use of expensive and/or toxic reagents and solvents. In view of these limitations and also with regard to yields, reaction time, toxicity, and catalytic loading, our method is believed to be superior to those previously reported.

chemistry [1, 2]. Among the different functional groups,

#### Results and discussion

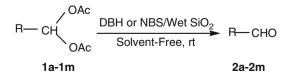

Recently, 1,3-dibromo-5,5-dimethylhydantoin (DBH) and N-bromosuccinimide (NBS) have gained much attention as oxidation and bromination agents in organic reactions [37– 39]. These compounds are relatively non-toxic, commercially available, inexpensive, and stable to air and moisture. In this work we examined the catalytic ability of DBH and NBS in the solvent-free deprotection of 1,1diacetates to the corresponding aldehydes using wet SiO<sub>2</sub> as a solid support. To achieve this, 1,1-diacetates 1a-1m were reacted with DBH or NBS in different molar ratios with or without use of wet SiO<sub>2</sub> to yield the corresponding aldehydes 2a-2m (Scheme 1). According to the experimental data reported in Tables 1 and 2, the best results were obtained when the reactions were carried out using wet SiO<sub>2</sub>. It is found that both aromatic and aliphatic 1,1diacetates were efficiently converted to their parent aldehydes with DBH and NBS, respectively, in 72-96% and 68-94% yields (Tables 1, 2) under mild reaction conditions. It is important to note that no conversion of the 1,1diacetates to aldehydes was observed when the reactions were carried out in the absence of either of these reagents.

Synthetically, chemoselectivity in chemistry is regarded as one of the most important aspects of organic reactions. In this regard, the selectivity of this method was investigated by conducting a competitive reaction on a 1:1 mixture of 1,1-diacetates derived from benzaldehyde and acetophenone (Scheme 2). As the <sup>1</sup>H NMR spectral analysis indicated, only the benzaldehyde diacetate was chemoselectively converted to benzaldehyde whereas the acetophenone diacetate remained intact under the same reaction condition. As a result, this procedure can be regarded as potentially useful for chemoselective deprotection of aldehyde diacetates in the presence of ketone diacetates.

Although the mechanism of this reaction is not yet fully understood, one possibility is suggested in Scheme 3. It is based on:

- $1 \quad reduction \ of \ reaction \ rates \ when \ dry \ SiO_2$  is used; and
- 2 the similar reactivities of aromatic and aliphatic aldehyde diacetates in these reactions.

As shown in this mechanism, possible in-situ release of bromide ion by DBH and NBS occurs [40, 41], and this ion

#### Scheme 3

1,1-diacetates derived from aldehydes. This reaction proceeds rapidly at room temperature to afford the product in excellent yield with no side product formation. Short reaction times, high yields, mild conditions, easy workup, absence of the solvent in the reaction, and the use of non-toxic, commercially available, and inexpensive reagents are the main advantages of this method that make it environmentally friendly and industrially applicable.

# **Experimental**

IR spectra were recorded on a Shimadzu 435-U-04 spectrophotometer (KBr). <sup>1</sup>H and <sup>13</sup>C NMR spectra were obtained by use of a Jeol FT NMR 90-MHz spectrometer; compounds were dissolved in CDCl<sub>3</sub> and TMS was used as internal reference. Melting points were determined on a stuart SMP3 apparatus. 1,1-Diacetates were prepared according to the literature [5, 6].

*General procedure for deprotection of 1,1-diacetates* 

A mixture of 1,1-diacetates **1a–1m** (1 mmol) and DBH (2.25–3.25 mmol) or NBS (2.25–4 mmol) and 0.1 g wet  $SiO_2$  (50% w/w) was placed in a mortar and pulverized at room temperature for an appropriate time (Tables 1, 2). After complete conversion of the substrate, as indicated by TLC, 10 cm<sup>3</sup> Et<sub>2</sub>O was added and the mixture was then directly absorbed on silica gel. Purification was accomplished by simple column chromatography using ethyl acetate and n-hexane as eluents. The pure products were obtained in good to excellent yields (Tables 1, 2).

Acknowledgments The authors wish to thank the University of Tarbiat Moallem Sabzevar and Bu-Ali Sina University in Hamadan

for financial support to carry out this research. We also thank Mrs Neda Rahiminezhad for her assistance.
