### Received May 5, 2004

A combined target-based and ligand-based drug design approach has been carried out to define a novel pharmacophore model of the human  $A_3$  receptor antagonists. High throughput molecular docking and comparative molecular field analysis (CoMFA) have been used in tandem to assemble a new target based pharmacophore model. In parallel, to provide more accurate information about the putative binding site of these  $A_3$  inhibitors, a rhodopsin-based model of the human  $A_3$  receptor was built and a novel Y-shape binding motif has been proposed. Dockingbased structure superimposition has been used to perform a quantitative study of the structureactivity relationships for binding of these pyrazolo-triazolo-pyrimidines to adenosine  $A_3$ receptor using CoMFA. Both steric and the electrostatic contour plots obtained from the CoMFA analysis nicely fit on the hypothetical binding site obtained by molecular docking. On the basis of the combined hypothesis, we have designed, synthesized, and tested 17 new derivatives. Consistently, the predicted  $K_i$  values were very close to the experimental values.

# Introduction

Many physiological functions may be regulated by interaction of adenosine with a set of specific receptors, classified as  $A_1$ ,  $A_{2A}$ ,  $A_{2B}$ , and  $A_3$ .<sup>1</sup> For this reason, adenosine receptors could be considered in the treatment of different pathophysiologic conditions.<sup>2-6</sup> Adenosine receptor subtypes belong to the family of seven transmembrane domain receptor coupled G proteins, and they exert their physiological role by activation or inhibition of different second messenger systems.<sup>2-6</sup>

 $A_3$  adenosine receptors are associated with cerebroprotection<sup>7,8</sup> and cardioprotection<sup>9</sup> effects of adenosine agonists and effects on the immune and inflammatory systems.<sup>3,10</sup> The  $A_3$  adenosine receptor subtype, recently cloned from different species (e.g. rat, human, dog, sheep),<sup>11,12</sup> is coupled to the modulation of at least two second messenger systems: inhibition of adenylate cyclase and stimulation of phospholipase C and D.<sup>11,12</sup> In human,  $A_3$  receptors have been found in several organs, such as lung, liver, kidney, and heart, and with a lower density in brain.<sup>9,11,12</sup> This receptor subtype is under examination in relation to its potential therapeutic applications. In particular, antagonists for  $A_3$  receptors seem to be useful for the treatment of inflammation and regulation of cell growth.<sup>2,13</sup> However, concerning specifically the potential treatment of inflammation, the role of both  $A_3$  agonists and antagonists is still ambiguous.<sup>3</sup>

In the last five years, many efforts have been conducted searching potent and selective human  $A_3$  adenosine antagonists. In this field several different classes of compounds, possessing good affinity (nM range) and with a broad range of selectivity, have been proposed.<sup>10,14,15</sup>

Recently, our group has synthesized a new series of pyrazolo-triazolo-pyrimidines bearing different substitutions at the N<sup>5</sup> and N<sup>8</sup> positions which have been described as highly potent and selective human A<sub>3</sub> adenosine receptor antagonists. Table 1 summarizes all the compounds (1–106) previously synthesized as human A<sub>3</sub> adenosine receptor antagonists.<sup>15–20</sup>

A combined target-based and ligand-based drug design approach has been carried out to define a novel pharmacophore model of the human  $A_3$  receptor antagonists. High throughput molecular docking and comparative molecular field analysis (CoMFA) have been used in *tandem* to assemble a novel target-based pharmacophore model. In parallel, to provide more accurate information about the putative binding site of these  $A_3$  inhibitors, a rhodopsin-based model of the human  $A_3$  receptor was built, and more than 100 pyrazolotriazolopyrimidine ligands were docked into the putative ligand binding site. A novel Y-shaped binding

Figure 1. Flowchart describing our combined target-based and ligand-based drug design approach.

motif has been proposed for this class of  $A_3$  inhibitors. Docking-based structure superimposition has been used to perform a quantitative study of structure–activity relationships using CoMFA. A remarkable correlation coefficient (cross-validated  $r^2_{\rm cv}$ ) of 0.840 was obtained. Both steric and electrostatic contour plots, obtained from the CoMFA analysis, nicely fit on the hypothetical binding site achieved by molecular docking. Following our computational approach, we have designed, synthesized, and tested 17 new derivatives. Consistently, the predicted  $K_i$ values were very close to the experimental values.

## **Results and Discussion**

Our computational strategy has been summarized in Figure 1. We decided to combine a target-based approach (high throughput docking) and a quantitative ligand-based methodology like CoMFA to improve our capability to design new potent and selective human  $A_3$  antagonists.

Starting from our recent rhodopsin-based model of the "resting state" of human A<sub>3</sub> receptor, we decide to perform high throughput docking to analyze the hypothetical binding conformation of more than 100 pyrazolotriazolopyrimidines recently synthesized and tested in our laboratory. Nowadays, the robustness of the different scoring functions to correctly predict the binding affinity of different ligands versus the corresponding target is very feeble, and this is particularly true in the case of ligand-GPCRs recognition.<sup>21-24</sup> In this study, we decided to use CoMFA as an "alternative" strategy to quantitatively address the binding properties of our pyrazolotriazolopyrimidine derivatives. In fact, after analyzing docking results, we utilized the superposition of all low energy docked conformations as structural input (supermolecule) for a conventional CoMFA. Both field analysis and quantitative regression model have been used to intrinsically validate the model. As already mentioned above, a remarkable correlation coefficient (cross-validated  $r_{cv}^2$ ) of 0.840 was obtained. On the basis of our combined approach, we have designed, synthesized, and tested 17 new derivatives. To severely test the quality of our model, we voluntarily designed antagonists with estimated activities from the micromolar to the sub-nanomolar range. Impressively, all predicted  $K_{i}$ values were very close to the experimental values. This is nice evidence that this combined approach is a good integration between a very consolidated target-based approach, such as molecular docking, and a solid quantitative ligand-based methodology such as CoMFA.

Molecular Modeling. 1. Building a Y-Shape Antagonist-Bound Model of Human A<sub>3</sub> Receptor. As already mentioned pyrazolo-triazolo-pyrimidines bearing different substitutions at the N<sup>5</sup> and N<sup>8</sup> positions have been described as highly potent and selective human A<sub>3</sub> adenosine receptor antagonists. To perform our combined target-based and ligand-based approach, we decided to theoretically depict the putative TM binding motif of pyrazolo-triazolo-pyrimidines on human A3 receptor. Following our recently reported modeling approaches,<sup>15,20,25,26</sup> we built an improved model of the human A<sub>3</sub> receptor, using the bovine rhodopsin crystal structure as template,<sup>27</sup> which can be considered a further refinement in building the hypothetical binding site of the A<sub>3</sub> receptor antagonists already proposed. Special care had to be given to the second extracellular (E2) loop which in bovine rhodopsin folds back over transmembrane helices limiting the size of the active site.<sup>27</sup> As Jacobson and coauthors have already demonstrated, amino acids of this loop could be involved in direct interactions with the ligands.<sup>28,29</sup> Details of the building model are given in the Experimental Section. As already reported, the recognition of classic  $A_3$ antagonists seems to occur in the upper region of the TM helical bundle. TMs 3, 5, 6, and 7 seem to be crucial for the recognition of both agonists and antagonists. As recently reported by Jacobson and collaborators,<sup>30</sup> a number of amino acid residues in the transmembrane domains 3, 5, and the second extracellular loop (EL2) were individually replaced with Ala and other amino acids. These residues are homologous to those that have been predicted in previous molecular modeling studies of adenosine receptor to be involved in the ligand recognition, including His95, Trp243, Ser247, Asn250, and Lys152. To recognize the hypothetical binding motif of this class of human A3 inhibitors, a molecular docking study has been carried out on all 106 pyrazolotriazolopyrimidine derivatives reported in Table 1. A multidocking protocol implemented by MOE has been utilized in this computational step (see the Experimental Section for details). Unfortunately, but as logically expected, we did not found any robust quantitative correlation between the experimental binding affinity and the theoretical interaction energies based on the scoring function of our docking protocol. However, our goal was to explore if a multidocking protocol could be used to define a target-based pharmacophore model. The first very interesting result obtained from our molecular docking studies is that all pyrazolotriazolopyrimidine derivatives share a common binding motif inside the TM region of human A<sub>3</sub> receptor. Just for simplifying the description of our results, we have selected derivative 5, as reference ligand. Indeed, the most energetically stable docked conformation is very similar for all the analyzed compounds. As shown in Figure 2, we identified the hypothetical binding site of the pyrazolotriazolopyrimidine moiety surrounded by TMs 3, 5, 6, and 7 with the furan ring and the N<sup>8</sup>-substituents pointing toward the EL2, and the carbamoyl moiety in the 5-position oriented toward the intracellular environment.

Moreover, the furan ring is positioned between TM5 and TM3 whereas the N<sup>8</sup>-substituents are surrounded by TM2 and TM7. We have defined this peculiar and highly conserved binding motif as the Y-shape binding

**Figure 2.** Left: General topology of the human  $A_3$  receptor model. Reference compound **5** (colored in magenta) is docking inside the trans-membrane recognition site (see Experimental Section for details). Side chains of some amino acids important for ligand recognition are highlighted. Right: Side view of the human  $A_3$  receptor TM recognition region. We selected some of our 106 docked antagonists, and we superimposed them to define a new Y-shaped pharmacophore model.

motif. Interestingly, this new target-based pharmacophore model is nicely coherent with all structureactivity relationships already collected on these pyrazolo-triazolo-pyrimidine analogues. Analyzing in detail our model, all pyrazolotriazolopyrimidine derivatives present the carbamoyl moiety in the 5-position surrounded by two polar amino acids: His95 (TM3) and Ser247 (TM6). This region seems to be very critical for the recognition of the antagonist structures. In fact, a major structural difference between the hypothetical binding sites in these receptor subtypes is that the  $A_3$ receptor does not contain the histidine residue in TM6 common to all  $A_1$  (His251 in hA<sub>1</sub>) and  $A_2$  (His250 in  $hA_{2A}$ ) receptors. This histidine has been shown to participate in both agonist and antagonist binding to A<sub>2A</sub> receptors.<sup>31</sup> In the A<sub>3</sub> receptor this histidine in TM6 is replaced with a serine residue (Ser247 in  $hA_3$ ). The stabilizing interactions among the carbamoyl moiety and these polar amino acids orient the carbamoyl phenyl ring in the middle of the TM bundle as clearly shown in Figure 2. In particular, the N-H of His95 (TM3) and the oxygen atom of the carbamoyl group are separated by 2.6 Å and appropriately oriented to form an Hbonding interaction. The side chain of Ser247 (TM6) is within hydrogen-bonding distance of NH of the carbamoyl group at 2.9 Å. According to the recently published mutagenesis results, His95 is crucial for ligand recognition, whereas Ser247 slightly affects the binding of both agonists and antagonists.<sup>30</sup> The receptor region around the phenyl ring of the carbamoyl moiety is mostly hydrophobic and characterized by three nonpolar amino acids: Ile98 (TM3), Ile186 (TM5), Leu244 (TM6). This environment could justify why polar substituents at the para position are not very well tolerated, as in the case of sulfonic acid group.<sup>15</sup> Evaluation of the ligand binding pocket of the receptor reveals that very limited empty space is present between TM5 and TM6 and, consequently, a steric control seems to take place around the para position of the phenyl ring. As already demonstrated, substituents at the para position of the  $N^5$ - phenyl ring induce a decrease of affinity at the human  $A_3$  adenosine receptors of about 2–5-fold with respect to the unsubstituted derivatives.<sup>15,26</sup> The same steric control takes place when substituents larger than hydrogen are present at the meta position of the phenyl ring. In this case a strong steric repulsion among substituents, at the meta position, and amino acid side chains of TM6 and TM7 could significantly reduce the affinity at the hA<sub>3</sub> receptor. On the contrary, substituents at the ortho position seem to occupy an empty region of the binding cavity. As previously described, in the chloro substituted series the change of the position (2- or 4-substitution) seems not to influence affinity at the hA<sub>1</sub>, hA<sub>2A</sub>, and hA<sub>2B</sub> receptors compared to the 3-chloro substituted compounds, maintaining it in the high nanomolar range (100-500 nM), while significant differences appeared in binding affinity to the hA<sub>3</sub> adenosine receptors (see Table 1).<sup>15</sup>

Another important and highly conserved interaction, probably a  $\pi - \pi$  interaction, is predicted among the furan ring of the pyrazolotriazolopyrimidine analogues and the two phenylalanine residues, Phe168 (EL2) and Phe182 (TM5), respectively. This interaction seems to be another important pharmacophore feature of our binding motif. Interestingly, the amino acids corresponding to Leu90 and Phe182 in the human A<sub>2A</sub> receptor were found to be essential for the binding of both agonists and antagonists.<sup>31,32</sup>

Moreover, another important and peculiar hydrophobic pocket delimited by nonpolar amino acids, Leu90 (TM3), Leu246 (TM6), and Ile268 (TM7), is also addressable in our binding site model. According to our docking studies, all the substituents at the N<sup>8</sup> position are located within this region of the receptor according to our binding hypothesis. However, two hydrophilic amino acids, such as Ser175 (EL2) and His272 (TM7), are present on the border of this hydrophobic pocked, and they can interact through hydrogen bonding in the presence of appropriate substituents. We have already

<sup>a</sup> Minimum s = 2.0. <sup>b</sup> Standard error of prediction (cross-validated) = (PRESS/(n - c - l))<sup>1/2</sup>, n = number of rows, c = number of components. <sup>c</sup> Ratio of  $r^2$  explained to unexplained =  $r^2/(l - r^2)$ . <sup>d</sup>  $r^2_{\rm bs} = r^2$  after bootstrapping. <sup>e</sup> Cross-validated  $r^2$  after leave-one-out procedure:  $r^2_{\rm cv} = (\text{SD} - \text{PRESS})/\text{SD}$ ,  $\text{SD} = (Y_{\rm actual} - Y_{\rm mean})^2$  and PRESS =  $\sum(Y_{\rm predicted} - Y_{\rm actual})$ . For further explanation of these mathematical formulas, see ref 40. <sup>f</sup> The std dev row belongs with the bootstrapping  $r^2$ .

published and rationalized that hydrophobic substituents are very well tolerated at the N<sup>8</sup> position.<sup>18</sup>

Finally, a strong hydrogen bonding interaction is possible between Asn250 (TM6) and the triazolo ring of the pyrazolotriazolopyrimidine moiety. In particular, the N–H of Asp250 and the N<sup>4</sup> of the triazolo ring group are separated by 2.5 Å and appropriately oriented to form an H-bonding interaction. Also this asparagine residue, conserved among all adenosine receptor subtypes, was found to be important for ligand binding.<sup>31,32</sup>

No direct interactions are predicted between the antagonist structure and the two polar amino acids Thr94 (TM3) and Ser97 (TM3). As previously reported, the corresponding two amino acids in the  $A_1$  and  $A_{2A}$  receptors, respectively, are important for the coordination of agonists, but not for antagonists.<sup>31,32</sup>

Molecular Modeling. 2. CoMFA as "Alternative" Scoring Function. In *tandem* with our molecular docking studies, a CoMFA methodology was applied to the data from the  $A_3$  binding assay as a means of identifying the structural features of pyrazolotriazolopyrimidine derivatives responsible for affinity. Our approach consists of utilizing CoMFA as a quantitative tool to predict the receptor binding affinity using the pharmacophore model based on the multidocking approach described above. PLS was used in conjunction with cross-validation to obtain the optimal number of components to be used in the subsequent analyses. PLS

**Figure 3.** Side view of the 5–A<sub>3</sub> complex model. The side chains of some crucial important residues in proximity ( $\leq$ 5 Å) to the docked pyrazolo-triazolo-pyrimidine molecule are highlighted and labeled: Leu90 (TM3), His 95 (TM3); Phe182 (TM5), Ile186 (TM5); Trp243 (TM6); Ser247 (TM6), Asn250 (TM6), Ser271 (TM7), His272 (TM7), Ser275 (TM7). The steric and the electrostatic contour plots, obtained from the CoMFA analysis, are included into ligand binding cavity. The yellow and the blue polyhedra correspond to regions of the field that are predicted to decrease the A<sub>3</sub> receptor affinity, while the green and the red regions are predicted to increase binding affinity.

analysis based on a least-squares fit gave a correlation with a cross-validated  $r_{cv}^2$  of 0.840, with the maximum number of components set equal to 6 (maximum number of components set equal to 4, 5, or 7 gave lower crossvalidated  $r_{cv}^2$  and the cross-validation groups set equal to the number of observations. The non-cross-validated PLS analysis was repeated with the optimum number of components, as determined by the cross-validated analysis, to give an  $r^2$  of 0.922. To obtain statistical confidence limits, the non-cross-validated analysis was repeated with 10 bootstrap groups, which yielded an  $r^2$ of 0.802 (optimum number of components was 6), SEP = 0.185, standard deviation = 0.022, steric contribution = 0.571, and electrostatic contributions = 0.429. The CoMFA-derived QSAR of pyrazolotriazolopyrimidine derivatives exhibited a good cross-validated correlation, indicating that it was highly predictive. Cross-validation provides information concerning the predictive ability of the QSAR data set by minimizing the occurrence of chance correlations in the QSAR model. The high bootstrapped  $r^2$  value and a small standard deviation suggest a high degree of confidence in the analysis. Fitted vs measured  $pK_i$  values for the CoMFA analysis of the human  $A_3$  training set are shown in Table 2.

The coefficients corresponding to each sampled field point in the resulting correlation equation were graphically contoured. Contours corresponding to the steric (green and yellow) and electrostatic (blue and red) fields are plotted together with compound **5** docked inside the human  $A_3$  binding cavity as shown in Figure 3.

The polyhedra describe the regions of space where the steric and the electrostatic fields are predicted by the CoMFA model to have the greatest effect on binding affinity. The yellow and the blue polyhedra correspond to regions of the field that are predicted to decrease the  $A_3$  receptor affinity, while the green and the red regions are predicted to increase binding affinity. As shown in

Figure 3, the proposed pharmacophore model fits very nicely within the transmembrane binding cleft. All steric and electrostatic features are coherent with the structure-activity relationship already described during the molecular docking analysis above. In particular, a green polyhedron, with a mean steric bulk favorable region, is found near the N<sup>5</sup>-carbamoyl moiety. As already described, this green polyhedron nicely fits with the receptor region around the phenyl ring of the carbamoyl moiety and characterized by three nonpolar amino acids: Ile98 (TM3), Ile186 (TM5), Leu244 (TM6). Moreover, from an electrostatic point of view the two red polyhedra around to N<sup>8</sup>-substituents and to the N<sup>5</sup>carbamoyl moiety are complementary respectively to Ser175 (EL2), His95 (TM3), Ser247 (TM6), and His272 (TM7). On the other hand, the blue polyhedron close to the N<sup>5</sup>-phenyl ring is surrounded by four nonpolar amino acids [Ile98 (TM3), Ile186 (TM5), Phe239 (TM6), and Leu244 (TM6)] and the most important electrostatic interactions are mediated by the corresponding CO-NH peptide bonds.

**Molecular Modeling. 3. Validation Set.** On the basis of both the target-based pharmacophore model and the CoMFA model as alternative scoring function, we have designed, synthesized, and tested 17 (107–123) new derivatives with a different spectrum of affinity at the human A<sub>3</sub> receptor. Compounds 107–123 (test set, shown in Table 2) were used to evaluate the predictive power of this CoMFA model. As in the calibration step, a good predictive ability with an  $r_{pred}^2 = 0.873$  for the compounds in the test set was obtained. Table 3 shows that the affinities of all the examined compounds were predicted within 0.25 log unit across a range of 2.00 log units. Impressively, the predicted  $K_i$  values were very close to the experimental values. In particu-

lar, derivative **111** (4-[3-(2-furan-2-yl-8-methyl-8*H*-pyrazolo[4,3-*e*][1,2,4]triazolo[1,5-*c*]pyrimidin-5-yl)ureido]-phenylacetic acid ethyl ester) is active in a sub-nano-molar range (0.82 nM) as correctly predicted by our regression model. Again, this is clear evidence that this combined approach is a nice integration between a very consolidated target-based approach, such as molecular docking, and a solid quantitative ligand-based methodology such as CoMFA.

Synthesis of the Validation Set. Compounds 107– 123 were prepared following the general synthetic strategy summarized in Scheme 1. Compounds 107– 123 were synthesized according to a well-known procedure for the synthesis of the pyrazolo[4,3-*e*]-1,2,4triazolo[1,5-*c*]pyrimidines, previously reported.<sup>14–18</sup>

Alkylation of 5-amino-4-cyanopyrazole **124** with the appropriate alkyl halide in dry dimethylformamide led to an approximately 1:4 mixture of the  $N^1$  and  $N^2$  regioisomers (**125**, **126**) as an inseparable mixture, used for the following steps without any further purification.

Pyrazoles (125 and 126) were reacted with 2-furoic acid hydrazide in diphenyl ether at 260 °C to yield the aminotriazoles 127 and 128 , which were in turn converted into the 5-amino-8-(substituted)-2-(2-furyl)-pyrazolo[4,3-e]-1,2,4-triazolo[1,5-c]pyrimidine derivatives by reaction with cyanamide in the presence of *p*-toluenesulfonic acid. After separation of N<sup>7</sup> (minor product) and N<sup>8</sup> (major product) regioisomers by flash chromatography, the dried compounds 107 and 108 were obtained in good overall yield. Final compounds 109–123 were obtained by reaction of amino compounds 5, 20, 107, and 108, with the appropriate isocyanate (129–132) in dioxane at reflux.

**Final Remarks.** Fundamental understanding of the molecular details of ligand/GPCR interactions remains

Scheme  $1^a$ 

<sup>*a*</sup> Reagents: (i) NaH, DMF, RX; (ii) 2-furoic hydrazide, Ph<sub>2</sub>O, 260 °C; (iii) NH<sub>2</sub>CN, 1-methyl-2-pyrrolidone, pTsOH, 140 °C, then flash chromatography; (iv) dioxane reflux, 18 h. For compounds **8** and **9** see ref 18.

very rudimentary. How agonist binding transforms a resting GPCR into its active form and the microscopic basis of binding site blockade by an antagonist are generally still unclear. We decided to utilize in tandem structure-based and ligand-based drug design strategies to improve our knowledge about the human A<sub>3</sub> receptor-antagonist recognition process. In particular, using this combined strategy we have identified common subtle structural features of pyrazolo-triazolo-pyrimidines which lead to enhanced potency or selectivity at A<sub>3</sub> receptors. To specifically address the hypothetical binding motif of pyrazolotriazolopyrimidine derivatives we have used a multiple docking strategy to identify a novel target-based pharmacophore model. Superimposition of all low energy docked conformations has been used to characterize the more conserved chemical features crucial to the recognition process (target-based pharmacophore) and their fit in the putative binding site of the receptor. On the basis of the proposed pharmacophore map, we can state that the receptor binding properties of different A<sub>3</sub> antagonist derivatives are due to recognition at a common region inside the receptor binding site and, consequently, a common electrostatic potential profile. Due to the poor predictivity of the current scoring functions, we have decided to use CoMFA as an alternative tool to quantitatively predict the ligand-receptor binding affinity. Consistently with this new combined pharmacophore hypothesis, we have designed, synthesized, and tested 17 new pyrazolotriazolopyrimidine derivatives with a different spectrum of affinity at the human  $A_3$  receptor. As already underlined, the predicted  $pK_i$  values were very close to the experimental values.

In conclusion, using our combined approach pyrazolo-triazolo-pyrimidine derivatives have served as structural scaffolds for enhancement of selectivity at human  $A_3$  receptors and as important modeling probes for the study of the human  $A_3$  receptor binding site. Moreover, we are deeply analyzing whether or not structurally unrelated antagonists would fit into the novel defined pharmacophore model.

# **Experimental Section**

**Computational Methodologies.** All molecular modeling studies were carried out on a 6 CPU (PIV 2.0-3.0 GHZ) Linux cluster running under openMosix architecture.<sup>33</sup>

Homology modeling, energy calculation, and docking studies have been done using Molecular Operating Environment (MOE, version 2003.03) suite.<sup>34</sup>

CoMFA is a three-dimensional QSAR method that operates on a set of ligands that have been superimposed to reflect their anticipated common receptor binding orientation. CoMFA models describe the extent to which the change in magnitude of the electrostatic and steric fields as a function of compound, sampled as a function of spatial position around the compound set, accounts for the variance in measured biological activity. CoMFA studies were performed on a Silicon Graphics Power Indigo2 R8000 workstation running SYBYL 6.5.<sup>35</sup> Quantum calculations used throughout this study were performed using MOPAC (version 7.0).<sup>36</sup>

Homology Model of the Resting State of Human A<sub>3</sub> Receptor. On the basis of the assumption that GPCRs share similar TM boundaries and overall topology,<sup>37</sup> a homology model of the human A<sub>3</sub> receptor was constructed. First, the amino acid sequences of TM helices of the resting state A<sub>3</sub> receptor were aligned with those of bovine rhodopsin, guided by the highly conserved amino acid residues, including the DRY motif (D3.49, R3.50, and Y3.51) and three Pro residues (P4.60, P6.50, and P7.50) in the TM segments of GPCRs. The same boundaries were applied for the TM helices of the A<sub>3</sub> receptor as were identified from the X-ray crystal structure for the corresponding sequences of bovine rhodopsin,  $^{27}$  the  $C_{\alpha}$ coordinates which were used to construct the seven TM helices for the human A<sub>3</sub> receptor. The loop domains of the human A<sub>3</sub> receptor were constructed by the loop search method implemented in MOE. In particular, loops are modeled first, in random order. For each loop, a contact energy function analyzes the list of candidates collected in the segment searching stage, taking into account all atoms already modeled and any atom specified by the user as belonging to the model environment. These energies are then used to make a Boltzmann-weighted choice from the candidates, the coordinates of which are then copied to the model. Any missing side chain atoms are modeled using the same procedure. Side chains belonging to residues whose backbone coordinates were copied from a template are modeled first, followed by side chains of modeled loops. Outgaps and their side chains are modeled last. Special caution had to be given to the second extracellular (E2) loop, which has been described in bovine rhodopsin to fold back over transmembrane helices,<sup>27</sup> and, therefore, it limits the size of the active site. Hence, amino acids of this loop could be involved in direct interactions with the ligands. The presence of a disulfide bridge between cysteines in TM3 and E2 might be the driving force to this peculiar fold of the E2 loop. Since this covalent link is conserved in all receptors modeled in the current study, the E2 loop was modeled using a rhodopsinlike constrained geometry around the E2-TM3 disulfide bridge. After the heavy atoms were modeled, all hydrogen atoms were added, and the protein coordinates were then minimized with MOE using the AMBER94 force field.<sup>38</sup> The minimizations were carried out by 1000 steps of steepest descent followed by conjugate gradient minimization until the rms gradient of the potential energy was less than 0.1 kcal mol<sup>-1</sup> Å<sup>-1</sup>.

Molecular Docking (Multidocking) of the Human A<sub>3</sub> Receptor Antagonists. All 106 antagonist structures were docked into the hypothetical TM binding site by using the MULTIDOCK docking program, which is part of the MOE suite. Conformational samplings were conducted within a userspecified 3D docking box, using the Tabu Search protocol<sup>39</sup> and MMFF94 force field.<sup>40</sup> MOE-Dock performs a user-specified number of independent docking runs (20 in our specific case) and wrote the resulting conformations and their energies in a molecular database file. The resulting docked complexes were subjected to MMFF94 energy minimization until the rms of the conjugate gradient was <0.1 kcal mol<sup>-1</sup> Å<sup>-1</sup>. Charges for the ligands were imported directly from the MMFF94 force field.

The interaction energy values were calculated as follows:  $\Delta E_{\rm binding} = E_{\rm complex} - (E_{\rm ligand} + E_{\rm receptor}).$ These energies are not rigorous thermodynamic quantities, but can only be used to compare the relative stabilities of the complexes. Therefore, these interaction energy values cannot be used to calculate binding affinities since changes in entropy and solvation effects are not taken into account.

**CoMFA: Data Sets and Binding Studies.** A total of 106 pyrazolo-triazolo-pyrimidine derivatives were included in the training set used to generate the CoMFA model for human  $A_3$  receptors (see Table 1).

The synthesis of all pyrazolo-triazolo-pyrimidine derivatives was reported in detail previously.15-20 Binding of [<sup>3</sup>H]MRE3008-F20 to CHO cells transfected with the human recombinant A<sub>3</sub> adenosine receptors was performed according to Varani et al.<sup>41</sup> Competition experiments were carried out in duplicate in a final volume of  $250 \,\mu\text{L}$  in test tubes containing 1 nM [3H] MRE3008-F20, 50 mM Tris HCl buffer, 10 mM MgCl<sub>2</sub>, pH 7.4, 100  $\mu L$  of diluted membranes (50  $\mu g$  protein/ assay), and at least 6-8 different concentrations of examined ligands. Incubation time was 120 min at 4 °C, according to the results of previous time-course experiments.<sup>41</sup> Nonspecific binding was defined as binding in the presence of 1  $\mu$ M MRE3008-F20 and was about 25% of total binding. Bound and free radioactivity were separated by filtering the assay mixture through Whatman GF/B glass-fiber filters using a Micro-Mate 196 cell harvester (Packard Instrument Company). The filter bound radioactivity was counted on Top Count (efficiency 57%) with Micro-Scint 20. The protein concentration was determined according to the Bio-Rad method with bovine albumin as reference standard.  $^{42}$ 

**CoMFA:** Molecular Superposition. The pyrazolotriazolo-pyrimidine moiety is believed to be a determinant key for binding interactions of described derivatives. The energetically more stable docking conformation has been used for all compounds, as input for the CoMFA field calculations.

CoMFA: Field Calculations and Regression Tech**niques.** The electrostatic and steric fields were sampled along a three-dimensional lattice encompassing all molecules in each receptor data set. The lattice consisted of 720 sample points based on a 2.0 Å lattice spacing with boundaries extending 4.0 Å beyond the largest structure in all directions. Lattice spacings of 0.75 and 1.5 Å were also used without improvements of the CoMFA results. The lattice points within the union volume of the superimposed structures were dropped. The probe used to calculate the CoMFA fields consisted of an sp<sup>3</sup> carbon atom with a +1 charge and a van der Waals radius of 1.52 Å. The steric and electrostatic fields were calculated separately for each molecule using respectively a Lennard-Jones 6-12 potential and a Coulombic potential with a 1/rdistance-dependent dielectric. The steric and electrostatic energies were truncated at 30 kcal/mol. The field values corresponding to the 720 sample points for each molecule, together with binding affinity data, were stored in a SYBYL Molecular Spreadsheet to facilitate statistical analysis.

Partial least squared (PLS) regression analysis<sup>43</sup> was performed on the human A<sub>3</sub> antagonist dataset using a subset of CoMFA field sample points falling with a standard deviation  $\leq 1.0$  kcal/mol. The steric and the electrostatic fields were scaled to equalize their weighting in the CoMFA models (SYBYL command "scaling CoMFA\_std"). PLS was performed using cross-validation to evaluate the predictive ability of the CoMFA models.<sup>44</sup> The optimal number of latent variables came from the cross-validation equation having the lowest standard error, and a significance level  $\geq 99.5\%$  was estimated using the stepwise *F*-test. Bootstrap analysis of the dataset was used to evaluate the statistical confidence limits of the results.<sup>44</sup> A  $\sigma$  value of 2.0 was adopted for both the cross-validated and non-cross-validated analysis.  $\sigma$  values of 1.0 or 0.5 did not significantly change the calculated  $r^2$ .

Initial PLS analyses were performed in conjunction with the cross-validation option (leave-one-out method) to obtain the optimal number of components to be used in the subsequent analyses of the dataset. The PLS analysis was repeated with the number of cross-validation groups set to zero. The optimal number of components was designated as that which yielded the highest cross-validated  $r^2$  values in the non-cross-validated (conventional) analyses. The final PLS analysis with 10 bootstrap groups and the optimal number of components was performed on the complete dataset.

The corresponding calibration equation (resulting from the simultaneous contribution of all the observations) was derived after the optimal dimensionality of each receptor model was established, by PLS analysis and cross-validation. The calibration equation with latent variables was then converted to the original parametric space represented by probe-ligand interaction energies. A 3D-QSAR whose coefficients were associated with statistically significant lattice locations was therefore derived. CoMFA coefficient contour maps were generated by interpolation of the pairwise products between the 3D-QSAR coefficients and the standard deviations of the associated energy variables.

**CoMFA: Test Sets.** The test sets consisted of 17 new synthesized molecules for the considered training set 107–123 (Table 2). These structures were chosen to maximize a uniform sampling of biological activity. All predicted activities for the test set molecules were calculated using the optimized CoMFA model. The results of the non-cross-validated calibration model on the test sets are summarized in Table 2.

**CoMFA: "Predictive"**  $r^2$  **Values.** The "predictive"  $r^2_{\text{pred}}$  was based only on molecules not included in the training set and is defined as explained by Marshall and co-workers.<sup>45</sup>

Chemistry. General. Reactions were routinely monitored by thin-layer chromatography (TLC) on silica gel (precoated  $F_{254}$  Merck plates) and products visualized with iodine or potassium permanganate solution. Infrared spectra (IR) were measured on a Jasco FT-IR 200 spectrophotometer. <sup>1</sup>H NMR were determined in  $CDCl_3$  or  $DMSO-d_6$  solutions with a Varian Gemini 200 spectrometer, peaks positions are given in parts per million ( $\delta$ ) downfield from tetramethylsilane as internal standard, and J values are given in hertz. Light petroleum ether refers to the fractions boiling at 40–60 °C. Melting points were determined on a Buchi-Tottoli instrument and are uncorrected. Chromatographies were performed using Merck 60-200 mesh silica gel. All products reported showed IR and <sup>1</sup>H NMR spectra in agreement with the assigned structures. Organic solutions were dried over anhydrous magnesium sulfate. Elemental analyses were performed by the microanalytical laboratory of Dipartimento di Chimica, University of Trieste, and were within  $\pm 0.4\%$  of the theoretical values for C, H, and N.

**General Procedures for the Preparation of 8-(Ar)alkyl-2-(2-furyl)pyrazolo[4,3-e]1,2,4-triazolo[1,5-c]pyrimidine** (**107, 108).** A solution of **124** (10 mmol) in 40 mL of DMF cooled to 0 °C was treated with NaH (60% in oil, 12 mmol) in several portions over 10 min. After 45 min, the appropriate alkyl halide (12 mmol) was added and the reaction mixture was allowed to warm to 25 °C and stirred for 3–5 h (TLC:EtOAc 1:1). The reaction was quenched by addition of H<sub>2</sub>O (80 mL), and the aqueous layer was extracted with EtOAc (5  $\times$  25 mL). The organic layers were recombined, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, and concentrated at reduced pressure, to afford the alkylated pyrazole (125, 126) as an inseparable mixture of  $N^1$  and  $N^2$ isomers (ratio approximately 1:4). This mixture of  $N^1\!\!-\!$  and  $N^2\!\!-\!$ substituted-4-cyano-5-amino pyrazoles (125, 126) was then dissolved in diphenyl ether (50 mL), and 2-furoic acid hydrazide (13 mmol) was added. The mixture was heated at 260 °C using a Dean-Stark trap for the azeotropic elimination of water produced in the reaction. After 2.5 h, the mixture was poured onto hexane (300 mL) and cooled. The precipitate of crude pyrazole-triazole derivatives (127, 128) was filtered off and utilized for the next step without further purifications. The crude residue was dissolved in N-methylpyrrolidone (40 mL), cyanamide (60 mmol) and p-toluenesulfonic acid (15 mmol) were added, and the mixture was heated at 160 °C for 4 h. Cyanamide (60 mmol) was added again, and the solution was heated overnight. Then the solution was diluted with EtOAc (80 mL) and the precipitate (excess of cyanamide) was filtered off; the filtrate was concentrated under reduced pressure and washed with water  $(3 \times 30 \text{ mL})$ . The organic layer was dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated under vacuum. The residue was purified by flash chromatography (EtOAc/light petroleum 3:7) for obtaining the major product (N<sup>8</sup> alkylated) (107, 108), which was obtained in a good overall yield.

**5-Amino-8-***n***-octyl-2-(2-furyl)-pyrazolo[4,3-***e***]<b>1,2, 4-tri-azolo[1,5-***c***]pyrimidine (107). Yield:** 45%; pale brown solid. IR (KBr): 3430–2950, 1680, 1655, 1620, 1550, 1450 cm<sup>-1</sup>. <sup>1</sup>H NMR (DMSO- $d_6$ )  $\delta$ : 0.78 (t, 2H, J = 7); 1.01–1.25 (m, 10H); 1.62–1.99 (m, 2H); 4.22 (t, 2H, J = 7); 6.67 (dd, 1H, J = 2, J = 4); 7.14 (d, 1H, J = 4); 7.57 (bs, 2H); 7.88 (d, 1H, J = 2); 8.58 (s, 1H). Anal. (C<sub>18</sub>H<sub>23</sub>N<sub>7</sub>O) C, H, N.

**5-Amino-8-cyclohexylmethyl-2(2-furyl)pyrazolo[4,3***e*]**1,2,4-triazolo[1,5-c]pyrimidine (108).** Yield: 38%; pale brown solid. IR (KBr): 3445-2960, 1675, 1650, 1615, 1555,  $1450 \text{ cm}^{-1}$ . <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>)  $\delta$ : 0.89–1.08 (m, 4H); 1.43– 1.49 (m, 4H); 1.71–1.89 (m, 1H); 4.08 (d, 2H, *J* = 6); 6.68 (dd, 1H, *J* = 2, *J* = 4); 7.14 (d, 1H, *J* = 4); 7.58 (bs, 2H); 7.89 (d, 1H, *J* = 2); 8.54 (s, 1H). Anal. (C<sub>17</sub>H<sub>19</sub>N<sub>7</sub>O) C, H, N.

General Procedure for the Preparation of 5-[[(Substituted)amino]carbonyl]amino-8-alkyl-2-(2-furyl)pyrazolo[4,3-e]1,2,4-triazolo[1,5-e]pyrimidine (109–123). Amino compound (5, 20, 107, 108) (10 mmol) was dissolved in freshly distilled dioxane (15 mL), and the appropriate isocyanate (129–132) (13 mmol) was added. The mixture was refluxed under argon for 18 h. Then the solvent was removed under reduced pressure, and the residue was purified by flash chromatography (EtOAc-light petroleum 7:3) to afford the desired compounds 109–123.

**5-[[(Cyclohexyl)amino]carbonyl]amino-8-methyl-2-(2-furyl)pyrazolo[4,3-***e***]<b>1,2,4-triazolo[1,5-***c***]pyrimidine (109).** Yield: 90%; white solid. IR (KBr): 3245–2950, 1675, 1615, 1600, 1520 cm<sup>-1</sup>. <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$ : 1.01–1.95 (m, 10H); 3.26–3.29 (m, 1H); 4.06 (s, 3H); 6.68 (dd, 1H, J = 2, J = 4); 7.25 (d, 1H, J = 4); 7.94 (d, 1H, J = 2); 8.72 (s, 1H); 8.73 (bs, 1H); 9.01 (bs, 1H). Anal. (C<sub>18</sub>H<sub>20</sub>N<sub>8</sub>O<sub>2</sub>) C, H, N.

**5-[[(***n***-Pentyl)amino]carbonyl]amino-8-methyl-2-(2-furyl) pyrazolo[4,3-***e***]<b>1,2,4-triazolo**[**1,5-c**]pyrimidine (**110**). Yield: 82%; white solid. IR (KBr): 3240–2970, 1670, 1620, 1600, 1510 cm<sup>-1</sup>. <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$ : 0.88 (t, 3H, J =7); 1.10–1.51 (m, 6H); 3.26–3.29 (m, 1H); 4.09 (s, 3H); 6.72 (dd, 1H, J = 2, J = 4); 7.26 (d, 1H, J = 4); 7.96 (d, 1H, J = 2); 8.72 (s, 1H); 8.73 (bs, 1H); 8.98 (bs, 1H). Anal. (C<sub>17</sub>H<sub>20</sub>N<sub>8</sub>O<sub>2</sub>) C, H, N.

**4-[3-(2-Furan-2-yl-8-methyl-8H-pyrazolo[4,3-e][1,2,4]-triazolo[1,5-c]pyrimidin-5-yl)-ureido]phenylacetic Acid Ethyl Ester(111).** Yield: 82%; pale gray solid. IR (KBr): 3250-2960, 1725, 1675, 1615, 1600, 1510 cm<sup>-1</sup>. <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$ : 1.23 (t, 3H, J = 7); 3.62 (s, 2H); 4.16 (q, 2H, J = 7); 6.72 (dd, 1H, J = 2, J = 4); 7.17 (d, 2H, J = 9); 7.26 (d, 1H, J = 4); 7.71 (d, 2H, J = 7); 7.76 (d, 1H, J = 2); 8.15 (s, 1H); 8.56 (bs, 1H); 11.13 (bs, 1H). Anal. (C<sub>22</sub>H<sub>21</sub>N<sub>8</sub>O<sub>4</sub>) C, H, N.

5-[[(Cyclohexyl)amino]carbonyl]amino-8-isopentyl-2-(2-furyl)pyrazolo[4,3-e]1,2,4-triazolo[1,5-c]pyrimidine(112). Yield: 87%; white solid. IR (KBr): 3250–2970, 1673, 1610, 1600, 1515 cm<sup>-1</sup>. <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$ : 0.88 (d, 6H, J = 6); 1.15–1.99 (m, 13H); 3.61–3.63 (m, 1H); 4.21 (t, 2H, J = 7); 6.65 (dd, 1H, J = 2, J = 4); 7.23 (d, 1H, J = 4); 7.97 (d, 1H, J = 2); 8.64 (bs, 1H); 8.81 (s, 1H); 9.00 (bs, 1H). Anal. (C<sub>22</sub>H<sub>28</sub>N<sub>8</sub>O<sub>2</sub>) C, H, N.

**5-[[(***n***-Pentyl)amino]carbonyl]amino-8-isopentyl-2-(2-furyl)pyrazolo[4,3-***e***]1,2,4-triazolo[1,5-***c***]pyrimidine (113). Yield: 87%; white solid. IR (KBr): 3245-2955, 1675, 1625, 1600, 1510 cm<sup>-1</sup>. <sup>1</sup>H NMR (CDCl<sub>3</sub>) \delta: 0.79–0.99 (m, 9H); 1.11–1.59 (m, 11H); 1.64–1.81(m, 2H); 4.35 (t, 2H, J = 7); 6.68 (dd, 1H, J = 2, J = 4); 7.25 (d, 1H, J = 4); 7.94 (d, 1H, J = 2); 8.63 (bs, 1H); 8.81 (s, 1H); 9.02 (bs, 1H).
