Received July 2, 2007

The readily available and enzymatically derived *cis*-1,2-dihydrocatechol 4 has been elaborated, over 11 steps including an Overman rearrangement, into the non-natural enantiomer, (-)-1, of the alkaloid lycoricidine [(+)-1]. Related chemistries have provided analogues 18, 19, and 26.

The lycorine-type *Amaryllidaceae* alkaloids (+)-lycoricidine [(+)-1], (+)-narciclasine [(+)-2], and (+)-pancratistatin [(+)-3] have been known for many years and have been isolated from, inter alia, plants of the genus *Amaryllidaceae* including the bulbs of narcissi and daffodils.¹ The potent biological properties of such compounds, particularly their carcinostatic and antiviral qualities, have resulted in their being considered for use as therapeutic agents.² For example, (+)-pancratistatin and some of its derivatives have been the subject of preclinical development studies as agents for the treatment of certain cancers.² This situation, together with the limited

availability of certain of these alkaloids from natural sources, has prompted a substantial body of work directed at the development of practical synthetic routes to these compounds and various analogues. The extensive efforts devoted to this matter have been the subject of a number of recent reviews.³ Work in the area continues unabated.⁴

As part of a continuing program to exploit readily available, microbially derived and enantiomerically pure *cis*-1,2-dihydrocatechols such as **4** as starting materials in chemical synthesis,⁵ we have developed and now report efficient synthetic sequences that enable the rather rapid

transformation of this material into *ent*-lycoricidine [(-)-1] and various congeners. Hudlicky and co-workers have exploited metabolite **4** and its enantiomer in cycloaddition and aziridination protocols culminating in elegant total syntheses of alkaloids 1-3 as well as various related (especially deoxygenated) systems.³ The present work is distinct in that very different protocols have been applied to compound **4** in order to obtain the title compounds.

The syntheses of 3-*epi-ent*-lycoricidine and that analogue lacking the methylenedioxy unit are shown in Scheme 1.

Thus, *cis*-1,2-dihydroxylation of the readily accessible *p*-methoxybenzylidene acetal derivative $5^{6,7}$ of metabolite 4

3684

under the UpJohn conditions⁸ followed by treatment of the resulting diol (6) with MOM-Cl in the presence of base afforded the previously reported⁷ compound 7 (59% from 5). Treatment of this last compound with DIBAL-H resulted in essentially completely regiocontrolled cleavage of the PMP-acetal residue within the substrate and formation of the alcohol 8^7 (84%) that was immediately protected, using standard conditions, as the corresponding MOM-ether 9 (90%). Oxidative cleavage of the PMB-ether residue within this last compound using DDQ then afforded alcohol 10 (95%), which was immediately converted into the corresponding mesylate 11 using a minor modification of the Crossland-Servis procedure.9 Reaction of compound 11 with sodium azide afforded the expected S_N2 product 12 (95%) from 10) that was reduced to the corresponding amine 13 (99%) using the Staudinger protocol.¹⁰ Subjection of compound 13 to reaction with the commercially available boronate ester 14 under Suzuki-Miyaura cross-coupling conditions¹¹ in a microwave reactor then provided the tricyclic compound 16 in 50% yield. Thus far, we have been unable to determine the precise order of events associated with the conversion $13 + 14 \rightarrow 16$ but presume that the cross-coupling reaction precedes the lactamization step. This last step contrasts with most other protocols³ for establishing the lactam ring of such isocarbostyrils that often involve the application of a modified Bischler-Napieralski cyclization reaction.^{3,12} Treatment of compound **16** with trimethylsilyl bromide at -30 °C¹³ resulted in cleavage of the MOMprotecting groups and formation of the corresponding triol **18** (43%). Reaction of boronate 15^{14} with compound **13** under the same conditions as just described afforded the coupling product 17 (69%) that then gave 3-epi-ent-lycoricidine (19) (44%) upon exposure to trimethylsilyl bromide.

The synthesis of the 4-deoxy analogue of compound **19** was achieved in a similar manner (Scheme 2). Thus, treatment of alcohol 8^7 with a mixture of triiodoimidazole, imidazole, and triphenylphosphine gave the iodide **20**⁷ (81%) that was immediately reduced with tri-*n*-butyltin hydride to

⁽⁵⁾ For reviews on methods for generating *cis*-1,2-dihydrocatechols by microbial dihydroxylation of the corresponding aromatics, as well as the synthetic applications of these metabolites, see: (a) Hudlicky, T.; Gonzalez, D.; Gibson, D. T. *Aldrichim. Acta* **1999**, *32*, 35. (b) Banwell, M. G.; Edwards, A. J.; Harfoot, G. J.; Jolliffe, K. A.; McLeod, M. D.; McRae, K. J.; Stewart, S. G.; Vögtle, M. *Pure Appl. Chem.* **2003**, *75*, 223. (c) Johnson, R. A. *Org. React.* **2004**, *63*, 117.

give the iodinated system 21^7 (85%). Subjection of the last compound to treatment with DDQ afforded alcohol 22 (96%) that was immediately converted into the corresponding mesylate 23 under standard conditions. Treatment of compound 23 with sodium azide afforded the expected product 24^7 (76% from 22) that was reduced directly to the amine 25^7 (96%) under Staudinger conditions. Suzuki–Miyaura cross-coupling of this last compound with boronate ester 15 followed by treatment of the product lactam (62%) with trimethylsilyl bromide then gave 4-deoxy-3-*epi-ent*-lycoricidine (26) in 92% yield.

The synthesis of *ent*-lycoricidine [(-)-1] followed very similar lines (Scheme 3) and involved initial reaction of alcohol 10 with trichloroacetonitrile in the presence of DBU to give the acetimidate 27. Subjection of this last compound to microwave irradiation in the presence of K₂CO₃¹⁵ resulted in an Overman rearrangement¹⁶ and the formation of the acetamide derivative 28 (65% from 10). To the best of our knowledge the conversion $27 \rightarrow 28$ represents the first example of such a rearrangement that involves a halogenated alkene and that is effected by microwave irradiation. Hydrolysis of amide 28 was achieved using DIBAL-H17 and provided amine 29 (89%) that could be subjected to a Suzuki-Miyaura cross-coupling reaction with boronate ester **15**. The ensuing lactam (83%) was treated with trimethylsilyl bromide to give *ent*-lycoricidine $[(-)-1]^{18}$ in 62% yield. The NMR, MS, and IR spectral data derived from this material were completely consistent with those reported for both the natural product¹⁸ and its enantiomer.¹⁸ Similarly, the specific rotation of our material {[α]_D = -141 (*c* 0.44, pyridine)} was consistent with that reported¹⁸ previously $\{[\alpha]_D = -164\}$ (c 0.45, pyridine) for (-)-1}. Final confirmation of structure followed a single-crystal X-ray analysis¹⁹ of the derived triacetate **30** (70%): mp = 224-228 °C (lit.¹⁸ mp = 205-

210 °C); $[\alpha]_D = -196$ (*c* 0.40, CHCl₃) {lit.¹⁸ $[\alpha]_D = -205$ (*c* 0.40, CHCl₃)}.

Given the availability of the enantiomer of starting material $4,^5$ the work detailed above will also provide access to (+)-lycoricidine [(+)-1]. Moreover, it seems reasonable to suggest that rather straightforward modifications to these reaction sequences should permit the efficient preparation of other members of the lycorine alkaloid class. Work directed to such ends is now underway in these laboratories and results will be reported in due course.

Acknowledgment. We thank the Institute of Advanced Studies and the Australian Research Council for generous financial support. Mr. José Basutto (Australian National University) is warmly acknowledged for helpful discussions.

Supporting Information Available: Full experimental procedures; crystallographic data and atomic displacement ellipsoid plot for compound **30** (CCDC no. 648758); ¹H and/ or ¹³C NMR spectra of compounds **18**, **19**, **26**, **29**, (–)-1, and **30**.
