## Abstract

In the present study, the nanocatalyst of imidazolium based ionic liquids (ILs) is synthesized for the fixation of carbon dioxide ( $\text{CO}_2$ ) under moderate conditions by utilizing a balloon of  $\text{CO}_2$  with commercially available epoxides. IL incorporated porous dendritic fibrous nanosilica (DFNS) catalyst (IL/DFNS) was designed and synthesized. The synthesized catalyst was characterized using  $\text{N}_2$  absorption desorption isotherm, XPS, SEM, EDX, TGA, HR-TEM, and AFM. For cyclic carbonate, an environmental friendly catalyst of porous IL/DFNS indicate highly impressive catalytic efficiency from  $\text{CO}_2$  through  $\text{CO}_2$  fixation and epoxides under mild condition. Attendance of polar hydroxyl and anion exchange nature groups of IL frame work to high surface area is known as the main aspect to be reliable for elevated catalytic efficiency and also advance in stability of catalyst and providing a proper recyclability.

## 1 Introduction

Because of environmental convenience and sustainable increasing from the usage of renewable sources and the rising concentration of emissions, the  $\text{CO}_2$  exploitation, as a green source of carbon for the manufacture of valuable added chemical intermediates is garnered higher attention in the recent studies [1–5]. Consequently, taking necessary steps to control the emission of the industrial raw materials by flue-gas capture and converting it to favorable economically competitive products are important tasks [2, 6–13]. In this regards, scholars across the globe are

currently concerning for invention of novel protocols that may properly capture the atmospheric CO<sub>2</sub> and then convert it to value-added substances [14–17]. However, there are different challenges in the case of developing green and highly efficient ways for CO<sub>2</sub> fixation reaction under green conditions [18–21].

The organocatalysis presents an alternative for the CO<sub>2</sub> fixation and activation utilizing small organic molecules that is known as catalysts. Recently, [22–29] *N*-heterocyclic carbenes (NHCs) [30–32], frustrated Lewis pairs (FLPs) [33–39], *N*-heterocyclic bases (NHCBs), [40–43] polyphenols, [44, 45] quaternary onium hydroxide/quaternary [46] onium salts (PTCs), and fluoroalcohols, silanediols with co-catalysts [47, 48] as well as ionic liquids (ILs) [49–53] are utilized as catalysts for catalytic CO<sub>2</sub> fixation and activation.

In recent years, the use of surfactant on soft templating is an efficient way to produce mesoporous silica (dendritic silica fibers morphology (DFNS)). For adsorption and catalysis approaches as support material, silica having this morphology are being examined. In order to access the functional materials more effectively, for reactants, the outward radial widening of these silicas has higher surface area. Moreover, DFNS possesses thermally stable, and intrinsic mesoporous properties and presents high activity. The DFNS is required to synthesis micro emulsion system, which has surfactant, water, and oil. Moreover, the particle size and DFNS morphology may be lightly manipulated utilizing co-surfactant and different co solvents [54–57].

Ionic liquids (ILs) is introduced as proper homogeneous catalysts [58] due to their outstanding physicochemical properties such as negligible wide liquid range, vapour pressure, excellent solubility, and high ionic conductivity [59]. Although ILs have many advantages but, in its recovery, their practical usages are restricted utilizing some difficulties that cause environmental and economic issues (i.e., pending catalytic reactions, their high viscosity not just limits their mass transfer but also causes their handling hard). In addition, the utilize of relatively large values of ILs can cause toxicological issues and is costly. To produce heterogeneous catalysts, these issues may be overcome by utilizing immobilization of ILs on solid supports [60–62].

The aim of this study is production of new imidazolium based ILs to be utilized as nanocatalyst in the CO<sub>2</sub> fixation with epoxides in order to provide cyclic carbonates in good to excellent yields in very moderate conditions. Imidazolium based ionic liquids are produced. To give IL, the synthesis approach is according to attach dodecyl bromide to imidazole ring to obtain dodecyl imidazole and pairing two dodecyl imidazoles by utilizing 1,3-Diamino-2,2-bis(bromomethyl)propane, subsequently. This IL attaching by etherification on DFNS nanoparticle surfaces (Scheme 1).

## 2 Experimental

### 2.1 General Procedure for the Preparation of IL

6 mmol of imidazole, 6 mmol of potassium hydroxide and 2 ml of dimethylsulfoxide were introduced into a 10 ml flask and were mixed by stirrer at room temperature for 2 h. Then, 5 mmol of dodecylboromide were added drop wise to the reaction mixture in 30 min. The mixture was stirred for another 4 h. Afterwards, 30 ml of water was added to the reaction mixture and then the flask contents were introduced into a separating funnel. The mixture was extracted with 30 ml batches of chloroform for five times. Then, the chloroform extracts were combined and washed with 30 ml batches of water for five times to remove unreacted imidazole. The chloroform extract was dried with excess of MgSO<sub>4</sub>. 1 mmole of 2,2-bis (bromomethyl) propane-1,3-diamine and 2.5 mmol of dodecyl imidazole were weighed and introduced into a 25 mL flask and subsequently the mixture was placed in a 150 °C oil bath. After 8 h, the reaction a dark brown gelatinous substance was obtained. For purification, the product was washed two times with acetone and three times with acetonitrile.

### 2.2 General Procedure for the Preparation of FPS

Tetraethyl orthosilicate (2.08 g) and tripolyphosphate (3.67 g) were dissolved in a solution of cyclohexane (30 mL) and 1-pentanol (1.5 mL). A stirred solution of CPB (1 g) and urea (0.5 g) in water (30 mL) was then added to the top mixture. The resulting mixture was

continually stirred for 45 min at room temperature and then placed in a teflon-sealed hydrothermal reactor and heated at 120 °C for 5 h. The FPS was then isolated by centrifugation, washed with deionized water and acetone, and dried in a drying oven.

### 2.3 Total Approach for the Synthesis of DFNS/3-Chloromopropyl MNPs

A mixture was prepared by mixing 200 mg of FeNi<sub>3</sub>/DFNS in 20 ml of THF followed by the addition of 20 mmol of NaH via ultrasonication. After that, 22 mmol of 3-chloromopropyl trimethoxysilane were added into the mixture at room temperature and stirred for 16 h at 50 °C. The resultant mixture was filtered and washed with ethanol and deionized water. The filtered solids were then dried in vacuum condition at 50 °C for 3 h.

### 2.4 Total Approach for the Synthesis of IL/DFNS NPs

DFNS/3-chloromopropyl (200 mg) are diffused in a solution (80 mL) of ethanol, deioned water (20 mL) and 28 wt% concentrated ammonia aqueous solution (NH<sub>3</sub>·H<sub>2</sub>O, 2.0 mL) and finally by adding 20 mg of IL. The produced suspension has been washed, repeatedly, after intense stirring filtered frequently and then dried under the temperature of 50 °C at air presence.

### 2.5 General Procedures for Preparation of Cyclic Carbonate

IL/DFNS NPs (5 mg) and epoxide derivatives (1 mmol) were charged into the reactor vessel without using any co-solvent.

The reactor vessel was placed under a constant pressure of carbon dioxide and then heated to 70 °C for 2 h. Then the reactor was cooled to ambient temperature, and the resulting mixture was transferred to a 50 mL round bottom flask. Upon completion, the progress of the reaction was monitored by TLC when the reaction was completed, EtOH was added to the reaction mixture and the KCC-1/IL/HPW NPs was separated by filtration. Then the solvent was removed from solution under reduced pressure and the resulting product purified by recrystallization using n-hexane/ethyl acetate.

## 3 Results and Discussion

In this study, solution of DFNS is synthesized with taking into account of reported approaches and after that became suitable utilizing (3-Chloropropyl)trimethoxysilane, followed by reductive amination for making the related co-immobilized IL. Scheme 2 shows this process.

The morphology of the produced nanoparticles of DFNS and IL/DFNS were evaluated by TEM and FE-SEM. Figure 1a demonstrated that there are silica fibers and layer of nonporous silica. Figure 1a and b shows TEM and FE-SEM images. As can be observed, the DFNS samples possess a wrinkled radial structure and additionally solid spheres with 400 nm diameter. Wrinkled fibers (7 nm) can be observed by close study of these images. These fibers commonly grown from the center of spheres and radially adjusted. Moreover, the wrinkled radial structure overlap makes the conical pores and this hierarchical open channel structure along with fibers may lead to transfer the mass of reactants for performing easier. In addition, it can rise access to active sites. As can be seen in Fig. 1b and d,

after modification, the morphology of DFNS did not vary from FE-SEM and TEM images of IL/DFNS NPs. TGA analysis of IL/DFNS NPs is proved in Fig. 2. The solvent deletion of physisorbed and chemisorbed on the IL/DFNS material surface causing the weight loss. Moreover, the weight loss in the temperature between 250–450 °C is near 28.1 wt%, which is related to the organic group

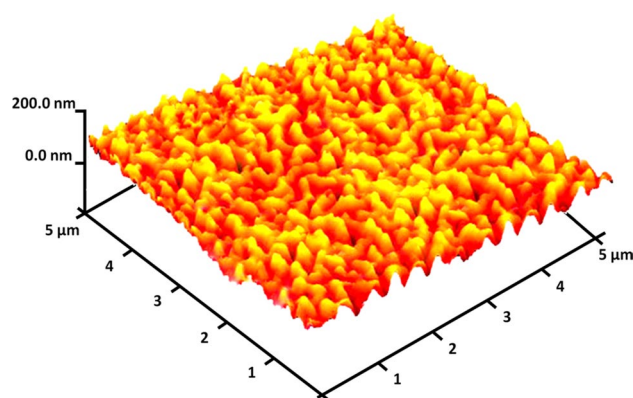

Fig. 5 Three-dimensional of AFM images of IL/DFNS NPs

Fig. 3 demonstrates a scheme of XPS. Peaks of C, O, Cl, and N are shown and the existence of N1s additional confirmed that DFNS are functionalized using the imidazolium. Moreover, the attendance of ions of  $\text{Cl}^-$  (the imidazolium counter ion) was specified by a sharp peak (in 287 eV). This demonstrates that there is imidazolium moiety into the catalyst. Figure 4 shows the origins in the catalyst that determined by EDX analysis. Figure 4 indicates the pattern of EDX showed whole the elements, which stand in IL/DFNS NPs like nitrogen, silicon, carbon, oxygen, and chlorine. These NPs level roughness is specified by AFM (atomic force microscopy) analysis. Figure 5 shows topographic scheme and the more height region demonstrated by the brighter yellowish white color enhanced by decreasing T/W, suggesting the increased in the level roughness of catalyst.

$\text{N}_2$  adsorption–desorption isotherm analysis is done to analyze the specific surface area and porosity of the products. In accordance to the BJH method, the mean pore

diameter and the specific surface area as well as the total pore volume values are shown in Table 1. The BET results demonstrated that the active surface area of the IL/DFNS and DFNS are equal to 348 and 671  $\text{m}^2 \text{g}^{-1}$ , respectively. The results of our experiments showed that the specific surface area decreased after melamine intercalation. In addition, the pore volume and average pore radius increased using melamine. It was determined that melamine intercalation has a more porous network structure.

In this apparatus, the conditions of reaction are optimized by propylene oxide and carbon dioxide for the production of cyclic carbonates catalyzed by nanoparticles of IL/DFNS. The influences of various parameters like time and solvent on the model reaction are presented in Table 2. Various solvents are utilized to study their effect on the synthesis of cyclic carbonates. Our outcomes indicated that no product is produced by polar protic solvents like isopropanol, methanol, ethanol, and water. Polar protic solvents like

EtOAc, DMF, and DMSO demonstrated that moderate performance in cross-coupling yields. In the present study, the outcomes indicated that solvents are less efficient compared to common heating under solvent-free conditions. The cross-coupling reaction efficiency in the case of carbonylation is higher in less polar solvents like toluene and/or anisole. The reaction is done under optimum conditions in the attendance of IL/DFNS NPs (10 mg) and the progress of reaction is analyzed by utilizing GC to study the reaction time. We found that proper product yields are archived after 120 min.

The influences of various factors for the model reaction are studied by IL/DFNS nanoparticles. As can be observed in Fig. 6, like other factors, the catalyst value is impressive in yields. In addition, low the product yields of the cycloaddition reaction are achieved in the lack of the catalyst. The cyclic carbonate products demonstrated moderate yields using weighted quantities of IL/DFNS NPs (1–4 mg). The optimum value of IL/DFNS NPs for the model reaction is determined to be 5 mg.

The effect of temperature on the reaction is shown in Fig. 7. As observed, cyclic carbonate production enhanced to around 98% at the temperature of 70 °C under 1.0 MPa CO<sub>2</sub> pressure after 120 min. Nevertheless, because of a negligible value of specific by products like olefin isomerization, a further enhance in temperature caused in a slight reduce in the amount of the product. Thus, for the parallel reactions of CO<sub>2</sub> and epoxide, the optimum temperature is around 70 °C. The pressure of CO<sub>2</sub> had a considerable influence on the parallel reaction. As observed in Fig. 8, the rate of reaction enhanced under pressures in the range of 0.8 and 1.0 MPa, rapidly. Based on previous works, we have concluded that enhancing the reaction pressure is desirable for cyclic carbonate synthesis until the pressure is below 1.0 MPa. Thus, the CO<sub>2</sub> pressure of 1.0 MPa is recognized as a particular condition. Initially, the following conditions are considered for the reaction: (the temperature of 70 °C at 4 h (10 mol%)). Various oxidants are utilized for enhancing yields of product. The reaction product is highly sensitive to the base.

**Fig. 6** Effect of increasing amount IL/DFNS NPs on yield of cyclic carbonate

**Fig. 7** Effect of temperature on yield of cyclic carbonate

As seen in Table 3, various epoxides are studied in the case of the investigation of the substrate scopes in this novel one-pot approach for the production of cyclic carbonates. Table 3 shows that, for all substrate, the catalyst is active. It is determined that glycidyl ethers (entry 4–12) are converted to their relating cyclic carbonates in high to excellent products, nevertheless, styrene oxides (entry 13–18) prepared carbonates in moderate products. The corresponding cyclic carbonates 2j as well as 2 k are achieved in good yields and moderate enantioselectivities while enantiopure styrene oxides 19 and 20 are utilized as substrates (78.3% and 66.7%), and the stereochemistry inversion of the cyclic carbonates may be due to the electron-withdrawing nature of the benzene ring that causes a nucleophilic ring opening of styrene oxide at the methylene bond and the methine bond.

We compared the catalytic performance of our catalyst with literature reported catalysts for the synthesis of cyclic carbonate. Table 4 clearly demonstrates that lower temperature, the minimum amount of catalyst, lower pressure of carbon dioxide and shorter reaction time were required for CO<sub>2</sub> transformation, using IL/DFNS NPs, while an appropriate, highly perfect, performance of the present catalyst was observed for the this reaction.

The mechanism of the bifunctional phase-transfer IL/DFNS NPs according to the experimental facts in the case

of the fixation of carbon dioxide with epoxides was suggested in Scheme 3. Firstly, epoxide was activated using IL/DFNS via hydrogen-bonding interaction among atoms of O and N–H for forming intermediate A that endures a nucleophilic attack of Cl<sup>−</sup> to provide intermediate B that then attacks carbon dioxide to get intermediate C, and after that the intramolecular ring-closing of intermediate C prepares cyclic carbonate with a IL/DFNS release to create the carbonate ready to the next catalytic cycle.

In the last step, we have done a leaching study to assay whether this catalytic approach is really heterogeneous or attended catalysis is increased homogeneously using some of IL materials leaching into the solution. Firstly, the reaction is conducted utilizing optimized conditions, in the attendance of a ten-runs reused batch of the catalyst. After a few minute, catalyst is taken by hot filtration and the remaining solution is stirred. Figure 9 indicates the CO<sub>2</sub> fixation vs time by a ten-runs reused catalyst batch (signed as a green curve),

and how no addition reagent utilize was identified when the catalyst was removed from the combination (signed as a red curve).

We have explored the scope for scale-up of organic chemistry using a large batch. We performed the reaction on five scales; 1 mol, 1.5 mol, 3 mol, 3.5 mol, and 5 mol, in each case running the reaction. It proved to be very scalable, affording isolated yields of 94%, 96%, 98%, 98%, and 97%, respectively, at the five reaction scales (Fig. 10). This unit should prove an effective tool for the development of scale-up chemistry.

The catalyst reusability of the IL/DFNS nanoparticles was additionally investigated. It was found that it can be reused up to ten times without high loss in its catalytic activity, an outlook necessary perspective of clean chemistry. The catalyst reusability of the IL/DFNS NPs up to successive ten-times, was additionally investigated for catalyst fixation of CO<sub>2</sub> under optimized conditions. It was demonstrated that

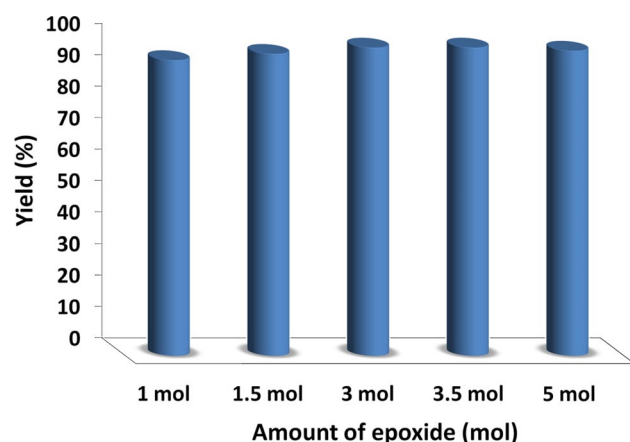

Fig. 10 Reactions performed in the scale-up

it can be reused for ten-times without considerable loss in its catalytic activity, a necessary perspective of clean chemistry. It can be rapidly recycled utilizing many washings by ethanol. Then, it is dried at 25 °C and was recycled for many times with approximately unaltered catalytic activity (refer to Fig. 11).

Finally, we have investigated after the passage of the 10th catalytic fixation of carbon dioxide at the specified premium conditions with some assay for ensuring whether the recovered catalyst structure was maintained or not (refer to Fig. 12). As can be seen in Fig. 12a XPS, pattern of the reproduced catalyst demonstrated that the structure of catalyst remained completely intact in recycling. In addition, the loading values of the organic materials in the nanoparticles of IL/DFNS are found after ten reuses using TGA. Figure 12b shows that their values are identical to the fresh nano composites. It should be noted that the nano catalyst has not detected any morphological variations, which is demonstrated using the FE-SEM schemes that obtained from the recovered catalyst as seen in Fig. 12c. As seen in Fig. 12d, the TEM scheme shown that the a generic gray and white layers placed on the direct chain of IL are IL/DFNS after the 10 th run.

## 4 Conclusions

Generally, under moderate conditions, a series of bifunctional IL/DFNS as phase-transfer catalysts for the fixation of CO<sub>2</sub> with epoxides were demonstrated to provide cyclic carbonates in good to excellent yields. These bifunctional catalysts were easily prepared and structure-tuneable, as well as prove high efficiency for the CO<sub>2</sub> fixation under ambient pressure. In addition, this catalyst are produced for the kinetic resolution of rac-epoxides using CO<sub>2</sub> for producing chiral cyclic carbonates.
