### Abstract

The first ternary chromium(III)–histidine–nucleotide complexes with purine and pyrimidine bases are described in the solid state. A histidine molecule of the starting chromium(III)–histidine complex is always removed during the reaction with the nucleotide. The starting histidine complexes and the ternary histidine–nucleotide–chromium(III) complexes have been characterized by elemental analyses, conductivity measurements, infrared and electronic spectroscopy, and by EPR and thermogravimetric analyses for the CMP derivatives. These results can afford more insight into chromium biochemistry.

### Introduction

The presence of chromium(III) in the glucose tolerance factor [1] has increased interest in chromium biochemistry and the study of model chromium compounds. There are some recent studies of chromium(III)–amino acid complexes and also nicotinic and glutathione complexes. Some of these complexes [2–5] present activity as analogues of glucose tolerance factor (GTF). There is also great interest in preparing chromium(III) nucleotide complexes as labels of allosteric enzymes [6] and finding out the role of chromium(III) in transcription processes and RNA and DNA interactions [7].

Recently Theophanides and Harvey have pointed out the interest in knowing the reaction properties of metal urea complexes [8]. We have observed a total substitution of urea molecules from  $\text{Cr}(\text{urea})_6\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  in reactions with nucleotides under mild conditions [9, 10].

The present paper studies the ternary system chromium(III)–histidine–nucleotide. Figure 1 gives the nucleotide structures and abbreviations used in this study.

Fig. 1. Nucleotide structures and abbreviations used.

### Experimental

The analyses of carbon, hydrogen and nitrogen were carried out with a Carlo Erba model 1106 microanalyzer at the Institute of Bio-organic Chemistry in Barcelona and with a Perkin-Elmer 240 B at the Faculty of Chemistry, Tarragona. The chlorine analysis was determined by the Schoniger method. Chromium was determined by using the colorimetric method for chromate [11]. The measurements were made with a Perkin-Elmer 552 UV–Vis spectrophotometer at 375 nm and 2 nm slit. The phosphorous content was determined by using the colorimetric method for phosphomolybdovanadate [12]. The measurements were carried out at 390 nm

and 2 nm slit. The conductivities were measured with a Crison 525 conductimeter at 20.0 °C in  $10^{-3}$  M complex solution. The infrared spectra were registered in the solid state (KBr pellets) on a Perkin-Elmer 683 IR spectrophotometer connected to a Perkin-Elmer 3600 data station. The reflectance spectra were recorded in the solid state on a Perkin-Elmer 552 UV-Vis spectrophotometer with an integrated sphere attachment. UV-Vis spectra were recorded in the same apparatus. The EPR spectrum of the CMP derivative was registered in the solid state at room temperature, on a Varian model E-12 in the X-band (Imperial College, London). The modulation frequency was 9.56 GHz.

The thermogravimetric analyses were recorded in a Mettler TA 3000 system at the Inorganic Chemistry Department, University of Granada (Spain).

The sources for nucleotides were Serva and Merck. The other products used were Merck. The starting  $\text{Cr(urea)}_6\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  complex was prepared according to procedure in the literature [13].

### Syntheses of Chromium(III)-Histidine Complexes

#### Synthesis of $\text{Cr(L-his)}_2\text{Cl}_3 \cdot 3\text{H}_2\text{O}$

$\text{Cr(urea)}_6\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  (1 mmol) was dissolved in 5 ml water and 2 mmol L-histidine in 10 ml water. The pH of the latter solution was raised to 8.97 with 2 N diluted NaOH ( $\text{pK}_3$  histidine = 8.97). Both solutions were mixed and the resulting dissolution ( $\text{pH} = 8.85$ ) was placed in a thermostatic bath at 45 °C for 8 h. At the end, a violet-red solution with  $\text{pH} = 3.6$  was obtained. The final solution was concentrated in a rotavapor at 45 °C to 5 ml volume and was eluted through a Sephadex G-10 column (diameter = 1 cm, length = 40 cm). Two fractions  $\text{F}_1$  and  $\text{F}_2$  were obtained. A precipitate was obtained by evaporating the  $\text{F}_1$  fraction.  $\text{F}_2$  is a very unstable green complex which in a 24 h period changes to violet, and could not be isolated. The precipitate obtained from  $\text{F}_1$  was vacuum dried over  $\text{P}_4\text{O}_{10}$  in a dessicator.

*Anal.* for  $\text{Cr(C}_6\text{H}_9\text{N}_3\text{O}_2)_2\text{Cl}_3 \cdot 3\text{H}_2\text{O}$ . Found (calc.): C, 28.21(27.56); H, 4.54(4.59); N, 16.51(16.08); Cl, 18.42(20.38); Cr, 8.84(9.95)%. The complex is violet and decomposes at 248–255 °C. It is soluble in water and has a millimolar conductivity at 20.0 °C of  $458 \Omega^{-1} \text{ cm}^2 \text{ mol}^{-1}$ . This measurement agrees with a 1:3 type electrolyte.

#### Synthesis of $[\text{Cr(L-his)}_2(\text{H}_2\text{O})_2]\text{Cl}_3 \cdot 3\text{H}_2\text{O}$

This synthesis is similar to the one for the former complex, but the initial pH in this case was 5.9, the  $\text{pK}_2$  value of L-histidine. The mixture was placed in a thermostatic bath at 45 °C for 14 h. The solution obtained was concentrated in a rotavapor to 5 ml and filtered through an analogous Sephadex G-10 column. A single fraction only was obtained in this case, and a precipitate was obtained by evaporating the

solution. The precipitate was vacuum dried over  $\text{P}_4\text{O}_{10}$  in a dessicator.

*Anal.* for  $[\text{Cr(C}_6\text{H}_9\text{N}_3\text{O}_2)_2(\text{H}_2\text{O})_2]\text{Cl}_3 \cdot 3\text{H}_2\text{O}$ . Found (calc.): C, 24.70(25.78); H, 4.75(5.01); N, 14.66(15.04); Cl, 21.68(19.07); Cr, 9.91(9.31)%. The complex decomposes at 165–170 °C and has a molar conductivity of  $478 \Omega^{-1} \text{ cm}^2 \text{ mol}^{-1}$ .

Working in the same way at initial pH 1.82 ( $\text{pK}_1$  of L-histidine) a blue solution was obtained, but we failed in the attempt to isolate a well defined complex.

#### Synthesis of $\text{Cr(L-his)}_2(\text{OH})\text{Cl}_2 \cdot \text{H}_2\text{O}$

$\text{Cr(urea)}_6\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  (2 mmol) was dissolved in 10 ml water and 2 mmol of L-histidine was dissolved in 10 ml water and the pH adjusted to 8.97 with 2 N diluted NaOH. Both dissolutions were mixed dropwise with continuous stirring and the resulting solution ( $\text{pH} = 8.56$ ) was placed in a thermostatic bath at 45 °C for 8 h. The final solution ( $\text{pH} = 2.6$ ) was concentrated in a rotavapor to 5 ml and eluted through a Sephadex G-10 column. Two fractions were eluted, firstly violet  $\text{F}_1$ , secondly blue-violet  $\text{F}_2$ . The second fraction was replaced in the thermostatic bath for 4 h and eluted again through the column; a single fraction was obtained. All the results indicated that it contained the same complex as  $\text{F}_1$ . The precipitate obtained by evaporating the  $\text{F}_1$  solution was vacuum dried over  $\text{P}_4\text{O}_{10}$ .

*Anal.* for  $\text{Cr(C}_6\text{H}_9\text{N}_3\text{O}_2)_2(\text{OH})\text{Cl}_2 \cdot \text{H}_2\text{O}$ . Found (calc.): C, 22.19(23.00); H, 4.32(3.83); N, 14.09(13.42); Cl, 21.61(22.68)%. The complex decomposes at 375 °C, is grey-violet and soluble in water with a millimolar conductivity of  $375 \Omega^{-1} \text{ cm}^2 \text{ mol}^{-1}$  which agrees with a 1:2 type electrolyte.

#### Synthesis of $[\text{Cr(L-his)}_2(\text{H}_2\text{O})_4]\text{Cl}_3$

The complex was obtained in a similar way to the previous one adjusting initial pH at 5.97 ( $\text{pK}_2$  of L-histidine). The solution was placed in a thermostatic bath and heated at 45 °C for 14 h (final  $\text{pH} = 2.36$ ). The solution was concentrated to 5 ml in a rotavapor and eluted through a Sephadex G-10 column; a single fraction was obtained but evidence of very small blue unstable second fractions was detected. A precipitate was obtained by evaporating the single fraction, the complex was vacuum dried over  $\text{P}_4\text{O}_{10}$ .

*Anal.* data for  $\text{Cr(C}_6\text{H}_9\text{N}_3\text{O}_2)_2(\text{H}_2\text{O})_4\text{Cl}_3$ . Found (calc.): C, 18.75(18.68); H, 4.02(4.41); N, 11.00(10.89); Cl, 28.69(27.63); Cr, 13.72(13.49)%. The product decomposes at 235 °C, is red and soluble in water with a millimolar conductivity of  $379 \Omega^{-1} \text{ cm}^2 \text{ mol}^{-1}$ . This value is intermediate for the expected 1:2 and 1:3 type electrolyte.

#### Synthesis of $\text{Cr(L-his)}_2(\text{urea})\text{Cl}_4 \cdot 2\text{H}_2\text{O}$

This complex was obtained in a similar way to the latter two but with an initial pH of 1.89 ( $\text{pK}_1$  of L-

histidine). The histidine–urea complex solution was placed in a thermostatic bath at 45 °C for 26 h. A blue solution with pH = 1.32 was obtained at the end. The solution was concentrated to 5 ml, the pH was raised with diluted 2 N NaOH to 3 and eluted through a Sephadex G-10 column. A single fraction was obtained. A precipitate appeared after evaporation of the solution and was vacuum dried over  $P_4O_{10}$ .

*Anal.* for  $Cr(C_6H_{10}N_3O_2)(CON_2H_4)Cl_4 \cdot 2H_2O$ . Found(calc.): C, 18.79(18.88); H, 3.96(4.04); N, 15.88(15.73); Cl, 28.93(31.91); Cr, 10.63(11.69)%. The complex decomposes at 144–145 °C, it is deep blue, very hygroscopic with a millimolar conductivity of  $590 \Omega^{-1} cm^2 mol^{-1}$ , which agrees with a 1:4 type electrolyte.

#### Syntheses of Ternary Chromium(III)–Pyrimidine Nucleotide–Histidine Derivatives

##### Syntheses of $Cr(5'CMP)(L-his)Cl_2 \cdot 7H_2O$ and $Cr_3(5'UMP)_3(L-his)(OH)Cl$

A 5 ml water solution containing 1 mmol of  $Cr(L-his)(OH)Cl_2 \cdot 7H_2O$  and a 5 ml water solution of 1 mmol disodium salt of 5'CMP or 5'UMP were mixed, pH of the mixture 3.5–3.6. The mixture was placed in a thermostatic bath at 45 °C for 11–16 h. The final solution was reduced to 5 ml in a rotavapor and eluted through a Sephadex G-10 column. Two fractions were obtained,  $F_1$  blue–green and  $F_2$  violet. By evaporating the solutions two precipitates were obtained. The second fraction complex appeared to be the starting complex and the first fraction complex contained the ternary derivatives that were dried over  $P_4O_{10}$ .

*Anal.* for  $Cr(5'CMP)(C_6H_9N_3O_2)Cl_2 \cdot 7H_2O$ . Found(calc.): C, 24.61(24.79); H, 4.25(4.96); N, 11.51(11.57); Cl, 10.30(9.78); Cr, 8.90(7.16); P, 5.33(4.27)%. The blue–grey CMP derivative is soluble in water, decomposes at 300 °C and has a millimolar conductivity of  $422 \Omega^{-1} cm^2 mol^{-1}$ . This value is greater than expected for a 1:2 type electrolyte. Protonation or dissociation equilibria either from histidine or nucleotide can increase the conductivity value.

*Anal.* for  $Cr_3(5'UMP)_3(L-his)(OH)Cl$ . Found(calc.): C, 27.22(27.57); H, 3.96(3.76); N, 9.76(8.77); Cl, 3.12(2.47); Cr, 10.27(10.86); P, 7.07(6.47)%. The grey UMP derivative is insoluble in water and unusual organic solvents and decomposes at 290 °C.

#### Attempts to Obtain Ternary Chromium(III)–Purine Nucleotide–Histidine Complexes

The syntheses using  $Cr(L-his)(OH)Cl_2 \cdot H_2O$  as starting product failed to obtain ternary complexes. Instead, binary compounds were obtained working under the same conditions as with the pyrimidine

derivatives. The  $F_1$  fraction eluted with 5'IMP was  $Cr_2(5'IMP)_2(OH)Cl \cdot 3H_2O$ . A precipitate is obtained with 5'GMP before elution:  $Cr_2(5'GMP)_2(OH)Cl \cdot 5H_2O$  and in the case of 5'AMP the complex previously described [10]  $Cr_2(5'AMP)_3 \cdot 10H_2O$ .

*Anal.* for  $Cr_2(5'IMP)_2(OH)Cl \cdot 3H_2O$ . Found(calc.): C, 26.36(26.59); H, 3.98(3.21); N, 13.08(12.41); Cl, 3.21(3.93); Cr, 11.17(11.52); P, 6.99(6.87)%. The IMP derivative is grey, decomposes at 260 °C and is soluble in water with a millimolar conductivity value of  $79 \Omega^{-1} cm^2 mol^{-1}$  which agrees with a 1:1 type electrolyte.

*Anal.* for  $Cr_2(5'GMP)_2(OH)Cl \cdot 5H_2O$ . Found(calc.): C, 25.66(24.78); H, 4.05(3.61); N, 14.66(14.46); Cl, 2.63(3.67); Cr, 9.29(10.74); P, 6.34(6.40)%. The pale blue GMP derivative is insoluble in water and usual organic solvents.

#### Syntheses of Chromium(III)–Nucleotide–Histidine Ternary Complexes

Owing to the substitution of one histidine molecule from the coordination sphere of chromium(III) in the reaction with purine nucleotides, the complex  $Cr(his)_2Cl_3 \cdot 3H_2O$  was used as starting product in the syntheses of ternary complexes.

A solution containing 1 mmol of  $Cr(L-his)_2Cl_3 \cdot 3H_2O$  dissolved in 5–10 ml water and a solution containing 1 mmol of the disodium salt of CMP, UMP, IMP, GMP and AMP were mixed (starting pH = 5.92, 5.92, 5.66, 5.56 and 5.80 respectively) and the mixture placed in a thermostatic bath at 45 °C for 21 h. A small amount of precipitate appeared and 50 ml of ethanol were added. The precipitate obtained was filtered off, washed with ethanol and vacuum dried over  $P_4O_{10}$ .

*Anal.* for  $Cr(5'CMP)(C_6H_9N_3O_2)(C_2H_6O) \cdot 2H_2O$ . Found(calc.): C, 33.60(33.50); H, 5.29(4.93); N, 14.60(13.75); Cr, 8.61(8.54); P, 4.72(5.09)%. The CMP ternary derivative is pink, decomposes at 270 °C and is soluble in water with a millimolar conductivity  $70 \Omega^{-1} cm^2 mol^{-1}$ . This value is greater than that expected for a non-electrolyte complex. Dissociation or protonation equilibria may be responsible for this conductivity value.

*Anal.* for  $Cr_3(5'UMP)_2(L-his)_4(EtOH)(OH) \cdot H_2O$ . Found(calc.): C, 34.73(34.00); H, 4.95(4.57); N, 13.90(14.42); Cr, 10.64(10.05); P, 4.67(3.99)%. The pink UMP derivative decomposes at 245 °C and has a millimolar conductivity of  $53 \Omega^{-1} cm^2 mol^{-1}$ .

*Anal.* for  $Cr(5'IMP)(C_6H_9N_3O_2)(EtOH) \cdot 4H_2O$ . Found(calc.): C, 31.27(30.77); H, 4.97(4.33); N, 15.55(15.71); Cr, 7.99(8.33); P, 4.69(4.97)%. The pink IMP derivative decomposes at 249–250 °C and is soluble in water with a millimolar conductivity of  $76 \Omega^{-1} cm^2 mol^{-1}$ .

*Anal.* for  $Cr(5'GMP)(C_6H_9N_3O_2)(EtOH) \cdot 4H_2O$ . Found(calc.): C, 33.65(34.23); H, 4.72(4.44); N, 18.65(17.75); Cr, 7.86(8.24); P, 4.87(4.91)%. The

pink GMP derivative decomposes at 265–270 °C, is insoluble in water and usual organic solvents.

*Anal.* for  $\text{Cr}(5'\text{AMP})(\text{C}_6\text{H}_9\text{N}_3\text{O}_2)(\text{EtOH}) \cdot 5\text{H}_2\text{O}$ . Found(calc.): C, 31.22(32.19); H, 4.87(5.37); N, 17.73(16.69)%. The pink AMP derivative decomposes at 238–240 °C and is soluble in water with a millimolar conductivity of  $148 \Omega^{-1} \text{cm}^2 \text{mol}^{-1}$ .

All the ternary complexes have the general formula  $\text{Cr}(\text{XMP}) \cdot (\text{L-his})(\text{EtOH}) \cdot n\text{H}_2\text{O}$  and a molecule of histidine has been substituted from the coordination sphere of chromium during obtention. The UMP tends to produce unclearly defined ternary complexes.

## Results and Discussion

### Chromium–Amino Acid Complexes

The chromium–amino acid complexes obtained were soluble and it was possible to measure their molar conductivities in water. The conductivity values are consistent with non-coordination of the  $\text{Cl}^-$  to chromium, except for the complex  $\text{Cr}(\text{L-his}) \cdot (\text{H}_2\text{O})_4\text{Cl}_3$  which has a millimolar conductivity value of  $379 \Omega^{-1} \text{cm}^2 \text{mol}^{-1}$ , intermediate value for electrolytes 1:2 and 1:3. Coordination of one chloride to the metal cannot be ruled out for this complex.

Table 1 records the infrared data for chromium amino acid complexes. Tentative assignments [14–18] have been carried out according to the literature.

The infrared band that appears at  $1636 \text{ cm}^{-1}$  in histidine, tentatively assigned as  $\nu_{\text{a}}\text{-COO}^-$ , appears in all the complexes as a strong band overlapping with the  $\delta\text{-NH}_2(\text{assym})$  band which appears at  $1595 \text{ cm}^{-1}$  in histidine. A frequency increase of  $20 \text{ cm}^{-1}$  is observed in  $\nu_{\text{a}}\text{-COO}$  for the complexes  $\text{Cr}(\text{L-his})_2\text{Cl}_3 \cdot 3\text{H}_2\text{O}$ ,  $[\text{Cr}(\text{L-his})_2(\text{H}_2\text{O})_2]\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  and  $\text{Cr}(\text{L-his}) \cdot (\text{OH})\text{Cl}_2 \cdot \text{H}_2\text{O}$ , which seems to indicate a strengthening of the carboxylic group. The  $\nu_{\text{s}}\text{-COO}^-$  band (at  $1416 \text{ cm}^{-1}$  in histidine) increases its frequency in all the complexes, appearing between  $1436\text{--}1445 \text{ cm}^{-1}$ , indicating coordination of chromium to the carboxylic group in all cases. Also  $\rho_{\text{r}}\text{-COO}^-$  (in histidine at  $541 \text{ cm}^{-1}$ ) shows changes in frequency or overlaps with other bands.

The imidazole group bands show important changes. The histidine bands at  $1273$  and  $1174 \text{ cm}^{-1}$  appear in the complexes as a single band in the area  $1268\text{--}1266 \text{ cm}^{-1}$ . The ring band at  $1065 \text{ cm}^{-1}$  shifts to  $1033\text{--}1028 \text{ cm}^{-1}$ ; the band that appears at  $1033 \text{ cm}^{-1}$  in  $\text{Cr}(\text{L-his})(\text{urea})\text{Cl}_2 \cdot 2\text{H}_2\text{O}$  may also be due to a urea molecule band. The stretching ring histidine band at  $977 \text{ cm}^{-1}$  shifts also to higher frequencies. The histidine bands at  $808$  and  $838 \text{ cm}^{-1}$  also show notable shifts in some cases.

In the  $470\text{--}460 \text{ cm}^{-1}$  area, weak bands are observed and tentatively assigned as Cr–N stretching bands, either from the amino or imidazole groups. In the  $350\text{--}340 \text{ cm}^{-1}$  area, weak bands are tentatively assigned as Cr–N stretching bands from the imidazole. No evidence of the presence of Cr–Cl stretching bands is observed. These results agree with the conductivity measurements.

Table 2 records the electronic spectra data. The average values of  $10 Dq$  and  $B'$  are calculated using the  $d^3$  Tanabe–Sugano diagram [19].  $\text{Cr}(\text{urea})_6\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  has a  $10 Dq = 16100 \text{ cm}^{-1}$  and  $B' = 651 \text{ cm}^{-1}$  [19] and  $\text{Cr}(\text{H}_2\text{O})_6^{3+}$   $10 Dq = 17400$  and  $B' = 695 \text{ cm}^{-1}$ . The green  $\text{F}_2$  unstable phase isolated during the obtention of  $\text{Cr}(\text{L-his})_2\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  presents maxima at  $617$  and  $450 \text{ nm}$ , leading to  $10 Dq = 16400 \text{ cm}^{-1}$  and  $B' = 548 \text{ cm}^{-1}$ . These results seem to indicate coordination of chromium(III) to O donor and N donors with an important nephelauxetic effect. These  $10 Dq$  and  $B'$  values are similar to complex  $\text{Cr}(\text{L-his})(\text{urea})\text{Cl}_4 \cdot 2\text{H}_2\text{O}$  values. A reaction mechanism of substitution of urea molecules where the carboxylic group of histidine is mainly responsible for the substitution can perhaps be inferred.

The  $10 Dq$  values increase with greater pH obtention values and  $B'$  decreases. The coordination sites of chromium(III) with histidine seem to be N amino, N imidazole and carboxylic groups in complexes obtained at pH 8.97 as starting pH, while the complexes obtained at starting pH = 5.97 seem to be coordinated only to N imidazole and carboxylic groups. The complex  $\text{Cr}(\text{L-his})(\text{urea})\text{Cl}_4 \cdot 2\text{H}_2\text{O}$  obtained at starting pH 1.82 has an average  $B'$  value of  $547 \text{ cm}^{-1}$ . This result is in accordance with the

$[\text{Cr}(\text{L-his})(\text{H}_2\text{O})_4]\text{Cl}_3$	579; 30.4	413; 34.8	17300	675
$\text{Cr}(\text{L-his})(\text{urea})\text{Cl}_4 \cdot 2\text{H}_2\text{O}$	579; 28.4	427; 27.8	17300	547

bonding of chromium to the carboxylic group of one urea molecule which has a significant nephelauxetic effect, greater than coordinated water. Comparison of these average values with those of  $[\text{Cr}(\text{L-his})\text{-(H}_2\text{O)}_4]\text{Cl}_3$  is clearly significant.

The number of histidine molecules coordinated to chromium also increases 10  $Dq$  and decreases  $B'$  values as expected.

*Derivatives Obtained from  $\text{Cr}(\text{L-his})(\text{OH})\text{Cl}_2 \cdot \text{H}_2\text{O}$  in Reaction with Nucleotides*

The CMP derivative is the only chromium–nucleotide–histidine ternary complex obtained from  $\text{Cr}(\text{L-his})(\text{OH})\text{Cl}_2 \cdot \text{H}_2\text{O}$ . The nucleotide 5'UMP leads to an insoluble, perhaps polymeric, complex of no structural interest. A total substitution of L-his coordinated to chromium is observed for the purine nucleotides. These results are similar to those previously described using  $\text{Cr}(\text{urea})_6\text{Cl}_3 \cdot 3\text{H}_2\text{O}$  as starting product reacting with nucleotides [8, 9].

The conductivity measurements agree with a 1:1 type electrolyte for the IMP derivative. The value of  $422 \Omega^{-1} \text{ cm}^2 \text{ mol}^{-1}$  in the conductivity measurement for  $\text{Cr}(5'\text{CMP})(\text{L-his})\text{Cl}_2 \cdot 7\text{H}_2\text{O}$  is close to that expected for a 1:3 electrolyte owing to protonation or dissociation equilibria either from the nucleotide or amino acid, or owing to the coordination of CMP to the chromium outer sphere through stacking interactions between the pyrimidine and imidazole rings: Masuda and Yamauchi [20] working with  $[\text{Pt}(\text{bipy})\text{-(en)}]^{2+}$  and 5'AMP [20] have established these stacking interactions by NMR, CD and X-ray diffraction studies.

Table 3 contains the infrared data for pyrimidine nucleotide derivatives. Histidine bands not overlapping with nucleotides appear at 1502, 1320, 1279 and  $617 \text{ cm}^{-1}$  in the CMP derivative. The carboxylic group asymmetric stretching band shifts  $6 \text{ cm}^{-1}$  to lower frequency indicating coordination to the carboxylic group. The stretching  $\text{C}=\text{O}$  band appears in the CMP complex at 1728 increasing its frequency due to hydrogen bonding [21–24] or to a histidine free carboxylic group [25].

The stretching symmetric phosphate band shifts to higher frequency. This result agrees with coordination of chromium to the phosphate group [21–24]. The UMP derivative clearly shows histidine bands at  $1391 \text{ cm}^{-1}$  ( $1416 \text{ cm}^{-1}$  histidine, carboxylic group stretching) and  $1465 \text{ cm}^{-1}$  ( $1465 \text{ cm}^{-1}$  in histidine, deformation of  $-\text{NH}_2$  group). The phosphate group bands also show shift to higher frequency.

Table 4 records the electronic data for these complexes. The d–d transitions present splittings owing to a distorted octahedral geometry. The shift for the  $\pi \rightarrow \pi^*$  band in the CMP ternary complex seems to indicate interaction of the base residue, either with the metal or a stacking interaction with the imidazole ring. The 10  $Dq$  average values of the order of  $17\,100 \text{ cm}^{-1}$  agree with a preferent coordination to O donors.

The UMP derivative clearly shows histidine bands at  $1391 \text{ cm}^{-1}$  ( $1416 \text{ cm}^{-1}$  histidine, carboxylic group stretching) and  $1465 \text{ cm}^{-1}$  ( $1465 \text{ cm}^{-1}$  in histidine, deformation of  $-\text{NH}_2$  group). The phosphate group bands also show shift to higher frequency.

The CMP ternary complex has a *g* value of 1.98 of chromium with an octahedral surrounding. The broad signal does not permit more information to be obtained. The thermogravimetric data for the CMP derivative (Table 5) are consistent with the ternary character of this complex.

#### *Ternary Chromium(III)–Nucleotide–Histidine Complexes Obtained from Cr(L-his)<sub>2</sub>Cl<sub>3</sub>·3H<sub>2</sub>O*

The general formula for these complexes is Cr(5'XMP)(L-his)(EtOH)·*n*H<sub>2</sub>O where 5'XMP is a purine or pyrimidine nucleotide. One of the histidine molecules of the starting complex has been substituted.

All the ternary complexes with the exception of the GMP derivative are water soluble, and conductivity measurements lead to millimolar conductivity values between 53 and 148  $\Omega^{-1} \text{ cm}^2 \text{ mol}^{-1}$ . These

values are greater than expected for a non-electrolyte and may be explained as protonation or dissociation equilibria either from the nucleotide or the amino acid, or due to coordination of the nucleotide to the outer sphere of chromium through stacking interactions between the bases and the imidazole ring [20].

Table 6 records the infrared data for pyrimidine nucleotide derivatives and Table 7 the purine nucleotide derivative.

The histidine bands at 1317, 653 and 625  $\text{cm}^{-1}$  appear with small shifts and the same shape in the ternary complexes.

The phosphate group stretching bands increase their frequency owing to interaction with the phosphate group. The carbonyl stretching bands appear in the CMP derivative at 1726 and 1717  $\text{cm}^{-1}$ , this may be due either to indirect coordination of the carbonyl group from the nucleotide through hydrogen bonding or to a free carboxylic group of histidine [25]. The ring band at 1531  $\text{cm}^{-1}$  in the free Na<sub>2</sub>CMP shifts changing its intensity to 1529  $\text{cm}^{-1}$ . The other ring bands show no clear information owing to the overlapping with histidine bands.

A weak band that appears at 351  $\text{cm}^{-1}$  has the same shape and intensity as the tentatively assigned stretching chromium–N imidazole band in the starting complex.

The doublet at 650, 625  $\text{cm}^{-1}$  of histidine appears in all three ternary purine nucleotide derivatives. Phosphate group bands also show a 15  $\text{cm}^{-1}$  increase in the frequencies. The C<sub>6</sub>=O carbonyl stretching band shows no significant change for IMP and GMP derivatives. The other strong ring bands show no change or overlap with histidine bands. The symmetric stretching of the carboxylic group band from histidine appears at 1413, 1419 and 1386  $\text{cm}^{-1}$  in the ternary GMP, IMP and 5'AMP derivatives. All the complexes present a weak band near 390  $\text{cm}^{-1}$  tentatively assigned as Cr–N stretching band.

The electronic data show average  $10 Dq$  values of  $17\,200\text{ cm}^{-1}$  and  $B'$  values of  $750\text{ cm}^{-1}$  (Table 4). These results agree with a mixed coordination to O and N donors indicating coordination to carbonyl groups of phosphate groups in the nucleotides. On the other hand, stacking interactions between bases and no direct coordination of chromium(III) to the nucleotide cannot be disregarded owing to the conductivity measurements and the lack of significant shifts of purine bands. Splitting of d–d bands owing to a distorted octahedral geometry was observed.

For the 5'CMP derivative a thermogravimetric study was performed (Table 5), clearly confirming the ternary character of the complex.

#### General Comment

The synthesis of ternary chromium(III)–nucleotide–histidine complexes is difficult owing to the tendency of nucleotides to substitute histidine molecules. This tendency was confirmed in our laboratory with other amino acids [26]. These facts may be important in understanding the behaviour of chromium(III) in biological systems. A chromium(III)–protein transport system may be changed by interactions with nucleotides, and the ternary Cr–protein–nucleotide complex may be responsible for biological activity. The study of other ternary systems Cr(III)–nucleotide–amino acid is in progress.

#### Acknowledgements

This work has received financial support from the 'Dirección General de Investigación Científica', project PB86-0074-02.

We wish to express our gratitude to Dr D. M. L. Goodgame, Imperial College, London, for the EPR measurements and to Dr J. M. Salas Pelegrin for the thermogravimetric measurements.
