Received July 31, 1997[®]

The reactivity of *cis*-bis(alkynyl)bis((diphenylphosphino)alkyne)platinum(II) complexes *cis*-[Pt(C≡CR)₂L₂] (R = Ph, Bu^t; L = PPh₂C≡CPh (L¹), PPh₂C≡CBu^t (L²); **1–4**), formed by displacement of the COD ligand from [Pt(C≡CR)₂(COD)], toward *cis*-[M(C₆F₅)₂(thf)₂] (M = Pt, Pd, thf = tetrahydrofuran; in both a 1:1 and 1:2 molar ratio) has been investigated. Treatment of **1–4** with 1 equiv of *cis*-[M(C₆F₅)₂(thf)₂] affords dinuclear derivatives [$\{\text{L}_2\text{Pt}(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CR})_2\}\text{M}(\text{C}_6\text{F}_5)_2\}$ (**5–12**) with exclusive formation of doubly alkynyl-bridged systems. The molecular structure of [$\{\text{(Bu}^t\text{C}\equiv\text{CPh}_2)_2\text{Pt}(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CPh})_2\}\text{Pd}(\text{C}_6\text{F}_5)_2\}$, **10**, is presented. In contrast, it was found that the course of the reactions with 2 equiv of *cis*-[M(C₆F₅)₂(thf)₂] strongly depend on the alkynyl substituents and metal centers. Thus, treatment of *tert*-butylalkynyl derivatives *cis*-[Pt(C≡CBu^t)₂L₂] (**2**, **4**) with 2 equiv of *cis*-[M(C₆F₅)₂(thf)₂] (M = Pt, Pd) only gives the expected trinuclear complexes **15A** and **18A**, in the case of the reactions with *cis*-[Pt(C₆F₅)₂(thf)₂]. The molecular structure of the complex [$\{\text{Pt}(\mu\text{-}\kappa(\text{P})\text{:}\eta^2\text{-PPh}_2\text{C}\equiv\text{CPh})_2(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CBu}^t)_2\}\{\text{Pt}(\text{C}_6\text{F}_5)_2\}_2\}$, **15A**, reveals that both the complexed *cis*-Pt(C₆F₅)₂ moieties are symmetrically linked to the precursor “*cis*-[Pt(C≡CBu^t)₂-(PPh₂C≡CPh)₂]”, with the platinum atoms connected by two unusual mixed alkynyl/phosphinoalkyne bridging systems. On the other hand, similar reactions of phenylethynyl derivatives (**1**, **3**) with 2 equiv of *cis*-[Pd(C₆F₅)₂(thf)₂] and **3** (L = PPh₂C≡CBu^t) with *cis*-[Pt(C₆F₅)₂(thf)₂] lead, instead, to the unexpected trinuclear PtPd₂ (**14B**, **17B**) and Pt₃ (**16B**) derivatives which display terminal phosphinoalkyne ligands and, hence, contain the alkynyl groups acting as $\mu_3\text{-}\eta^2$ (σ -Pt edge Pd or Pt) bridging ligands. However, a mixture of both types of isomers **13A** and **13B** (50:32) is observed in the reaction system *cis*-[Pt(C≡CPh)₂-(PPh₂C≡CPh)₂] (**1**)/*cis*-[Pt(C₆F₅)₂(thf)₂]. The following order of bonding capability is deduced from this study: alkynyl > *P*-bonded phosphinoalkyne and XC≡CPh fragments > XC≡CBu^t (X = Pt, P).

Introduction

Phosphinoalkynes and acetylides have been widely used in the formation of organometallic complexes containing two or more transition metals. Phosphinoalkynes (PPh₂C≡CR) are potentially difunctional ligands with the capacity to coordinate as simple phosphines¹ or disubstituted acetylenes² or to simultaneously use the phosphorus lone pair and the acetylenic π -orbitals in a polydentate bonding mode.³ Although all three of these possibilities have been observed, it seems that the coordinating ability of PPh₂C≡CR is usually dominated by the phosphine donor sites, especially for complexes of metals in their normal oxidation states. The participation of the acetylenic triple bonds in coordination

seems to require a low-valent metal site with a high affinity for alkyne π -electrons.^{2,3} These bonding situations are well represented by the low-valent dinuclear complexes [Fe₂($\mu\text{-}\eta^3\text{-PPh}_2\text{C}\equiv\text{CPh})_2(\text{CO})_6$],^{3c} [Ni₂($\mu\text{-}\eta^3\text{-PPh}_2\text{C}\equiv\text{CBu}^t$)₂(CO)₂],^{3f} [M₂($\mu\text{-}\eta^3\text{-PPh}_2\text{C}\equiv\text{CPh})_2(\text{PPh}_3)_2$] (M = Pt, Pd)^{3g} (Scheme 1, **A**), and [Fe₂($\mu\text{-}\eta^3\text{-PPh}_2\text{C}\equiv\text{CBu}^t$)(CO)₈]^{3d} (Scheme 1, **B**), in which the PPh₂C≡CR groups act as four-electron bridging ligands (*P*, η^2) and by the tetranuclear [Co₄($\mu_3\text{-}\eta^3\text{-PPh}_2\text{C}\equiv\text{CR})_2(\text{CO})_{10}$]^{3a} and trinuclear [Ni₂Cp₂($\mu_3\text{-}\eta^3\text{-PPh}_2\text{C}\equiv\text{CPh})\text{Ni}(\text{CO})_3$]^{2b} derivatives in which the ligands behave as six-electron donors (*P*, $\eta^2\text{:}\eta^2$, Scheme 1, **C**). In this context, we have recently shown that the reaction of *cis*-[MCl₂(PPh₂C≡CPh)₂] (M = Pt, Pd) with *cis*-[Pt(C₆F₅)₂(thf)₂] gives the unusual dinuclear derivatives [(C₆F₅)₂Pt(μ-Cl)(μ- $\eta^3\text{-PPh}_2\text{C}\equiv\text{CPh}$)-MCl(PPh₂C≡CPh)]⁴ (Scheme 1, **D**) containing a diphen-

Scheme 1

yl(phenylethynyl)phosphine acting as a bridging ligand (μ -P: η^2) between two Pt(II) centers. The formation of these derivatives is rather surprising since the isomeric dinuclear doubly bridging chloride complexes $[(\text{C}_6\text{F}_5)_2\text{Pt}(\mu\text{-Cl})_2\text{M}(\text{PPh}_2\text{C}\equiv\text{CPh})_2]$ would have been expected. Interestingly, we observed that these complexes **D**, which are sparingly soluble in common organic solvents, dissolve in CD_2Cl_2 , yielding a mixture of the isomers **D** along with the expected $\text{M}(\mu\text{-Cl})_2\text{Pt}$ derivatives. This fact suggests that in solution the migration of the $\text{Pt}(\text{C}_6\text{F}_5)_2$ unit around the $\text{cis-PtCl}_2(\text{PPh}_2\text{C}\equiv\text{CPh})_2$ fragment $[\mu\text{-Cl}, \kappa(\text{P}): \eta^2] \rightarrow (\mu\text{-Cl})_2$ probably has a small energetic cost and that steric effects involving the two mutually *cis* bulky $\text{PPh}_2\text{C}\equiv\text{CPh}$ groups should account in part for the $\mu\text{-}\eta^3\text{-PPh}_2\text{C}\equiv\text{CPh}$ bridging preference in the solid phase.

On the other hand, the ability of alkynyl ligands to bind several metal centers through σ and π bonds is now firmly established.⁵ In particular, we have recently found that either neutral or anionic alkynylplatinum substrates $[\text{L}_n\text{M}(\text{C}\equiv\text{CR})_2]^{n-}$ ($n = 0$, L = phosphine, COD; $n = 2$, L = C_6F_5 , $\text{C}\equiv\text{CR}$) react with Lewis-acidic metal complexes yielding homo- and hetero- di- and

trinuclear compounds stabilized with double alkynyl bridges, $\text{Pt}(\mu\text{-C}\equiv\text{CR})_2\text{M}$.^{5a,6}

In this paper, we report on the synthesis of neutral *cis*-bis(alkynyl)bis((diphenylphosphino)alkyne)platinum(II) complexes *cis*-[Pt(C≡CR)₂L₂] (R = Ph, Bu⁺; L = PPh₂C≡CPh, PPh₂C≡CBu⁺) and describe their reactivity toward *cis*-[M(C₆F₅)₂(thf)₂] (M = Pt, Pd) in either a 1:1 or 1:2 molar ratio. The syntheses of both di- and trinuclear complexes and the solid-state structures of [{(Bu⁺C≡CPh₂P)₂Pt(μ-η¹:η²-C≡CPh)₂}Pd(C₆F₅)₂], **10**, an unusual triplatinum [{Pt(μ-κ(P):η²-PPh₂C≡CPh)₂(μ-η¹:η²-C≡CBu⁺)₂}Pt(C₆F₅)₂]₂], **15A**, and an unprecedented triangular trimetallic biccapped [{(PPh₂C≡CBu⁺)₂Pt(μ₃-η²-C≡CPh)₂}Pt(C₆F₅)₂]₂] complex, **16B**, are presented.

Results and Discussion

Syntheses of *cis*-[Pt(C≡CR)₂L₂] Complexes. A

series of stable mononuclear σ -alkynyl/ P -coordinated (diphenylphosphino)alkyne complexes *cis*-[Pt(C $\equiv$ CR)₂L₂] (R = Ph or Bu^t; L = PPh₂C $\equiv$ CPh (L¹), PPh₂C $\equiv$ CBu^t (L²); **1–4**) are easily prepared in high yield by displacement of the weakly coordinating COD ligand from [Pt-(C $\equiv$ CR)₂COD] (R = Ph, Bu^t) derivatives by the appropriate diphenylalkynylphosphine ligands (eq 1). They are isolated as white solids, and their spectroscopic data (Tables 1 and 2) unequivocally confirm the P -coordination mode of the difunctional PPh₂C $\equiv$ CR

ligands: (i) the presence of strong absorptions (one for **1** and **2** or two for **3** and **4**) in the 2167–2208 cm⁻¹ region due to the ν(C≡C) of the phosphinoalkyne ligands shows that these groups are acting as P-donors. Complexes **1**, **3**, and **4** display additional absorptions of medium intensity in the 2117–2131 cm⁻¹ region attributed to the ν(C≡C) of terminal alkynyl ligands. (ii) The presence of a singlet in the ³¹P{¹H} NMR (δ -5.87, -7.90), especially the magnitude of ¹J_{Pt-³¹P} (2311–2360 Hz) which is comparable to that reported for mononuclear platinum complexes having a tertiary phosphine *trans* to a terminal alkynide group, is consistent with a *cis* configuration of the ligands about platinum.^{6,7} In the ¹³C NMR spectra, the acetylenic carbons (see Table 3 and Experimental Section for details) are found in the typical chemical shift ranges (C_α/C_β, Pt-C_α≡C_β-R 84.7–102.3/108.8–117 ppm; P-C_α≡C_β-R 70.7/118.3 ppm). The C_α signals are observed as a first-order doublet of doublets (Pt-C_α) or as a doublet (P-C_α, dd for **1** and **2**), while the alkyne C_β resonances exhibit the typical A part of a second-order AXX' system. The two alkynyl (Pt-C_α≡C_βR) carbon signals could be easily identified due to their significantly different coupling constants to the ¹⁹⁵Pt nuclei. The magnitude of the coupling constants ¹³C-¹⁹⁵Pt (¹J_{C-Pt} = 1135–1150 Hz, ²J_{C-Pt} = 309–314 Hz) are comparable to those observed in similar neutral bis-(alkynyl) complexes of the type [Pt(C≡CR)₂L₂] (L = phosphine)⁸ but, as expected, are notably larger than those observed by us in the anionic derivatives [Pt(C≡CR)₂X₂]²⁻ (X = C≡CR or C₆F₅) (924–1048)/250–293 Hz ¹J_{C-Pt}/²J_{C-Pt}).⁹ Although all complexes (**1–4**) exhibit signals due to the molecular peaks in the FAB(+) mass spectra, the most intense peaks correspond to the loss of the two alkynyl groups [PtL₂]⁺ (100), and the peaks assignable to the loss of one alkynyl ligand [Pt(C≡CR)L₂]⁺ are also present.

Syntheses of Dinuclear Complexes. In order to develop the synthetic potential of these σ-bonded species *cis*-[Pt(C≡CR)₂L₂], we have studied their reactivity toward *cis*-[M(C₆F₅)₂(thf)₂] (M = Pt, Pd). As shown in eq 2, treatment of *cis*-[Pt(C≡CR)₂L₂] with 1 equiv of *cis*-[M(C₆F₅)₂(thf)₂] (M = Pt, Pd) in CH₂Cl₂ at room temperature affords the homo- or heterobinuclear derivatives [{L₂Pt(μ-η¹:η²-C≡CR)₂]M(C₆F₅)₂] (**5–12**) in good yield. These complexes, isolated as white microcrystalline solids, are moderately air-stable in the solid state

but in solution they decompose in a few hours. The structural characterization of these dinuclear compounds is based on microanalysis, positive ion FAB mass spectrometry, and spectroscopic methods (IR (Table 1) and ¹H, ¹⁹F, and ³¹P NMR (Table 2)). In agreement with a dimeric formulation, the FAB(+) mass spectra show the expected peak corresponding to the molecular ion in most of the complexes (Table 1).

The presence of terminal phosphinoalkyne ligands is inferred from the IR spectra. Thus, all complexes show ν(C≡C) absorptions assignable to the phosphinoalkyne ligands which lies approximately in the same region as in the corresponding mononuclear derivatives. As in the precursors, complexes **5–8** (L = PPh₂C≡CPh) only exhibit one strong ν(C≡C) absorption (range 2179–2175 cm⁻¹), while in the PPh₂C≡CBu^t complexes (**9–12**), two absorptions in the range 2212–2168 cm⁻¹ are seen. One is assigned to ν(C≡C), and the other one is assigned to a Fermi resonance observed in substituted *tert*-butylalkynes.¹⁰ Moreover, in concordance with the η²-coordination of the alkynyl entities, some of the compounds (**6–8** and **12**) also show additional weak (C≡C)

absorptions at lower frequencies (range 2068–2040 cm^{-1}), which is in keeping with the presence of bridging alkynyl ligands. Unfortunately, this expected absorption assignable to the $\text{Pt}(\mu\text{-C}\equiv\text{CR})_2\text{M}$ moiety is not observed in the rest of the complexes. So, in order to confirm the assignment made above, an X-ray diffraction study has been carried out on a single crystal of one of the complexes, **10**. A drawing of the structure is presented in Figure 1, and selected bond distances (Å) and angles (deg) are collected in Table 4. A relevant feature of this structure is the presence of a palladium atom coordinated to two mutually *cis*- σ - C_6F_5 groups and stabilized by a chelating bis(alkynyl)platinum(II) fragment “*cis*-[$\text{Pt}(\text{C}\equiv\text{CPh})_2(\text{PPh}_2\text{C}\equiv\text{CBu}^t)_2$]” through unusual η^2 -alkynide interactions. In spite of the fact that the reactivity of alkynes toward palladium(II) complexes has been extensively explored,¹¹ only a few complexes

Scheme 2

containing an η^2 -palladium(II)–alkyne moiety have been reported.^{6c,9,12} These types of complexes have been proposed as intermediates in the final formation of unusual molecules arising from insertion and/or polymerization processes at the Pd(II) center.¹³ Due to the peculiar ability of bis(alkynyl)platinum substrates to stabilize unusual η^2 -metal–alkyne interactions, we have previously isolated and reported the first two examples [*cis*- $\text{Pt}(\text{C}_6\text{F}_5)_2(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CSiMe}_3)_2]\text{Pd}(\eta^3\text{-C}_3\text{H}_5)]^-$ ^{6c} and [*cis*-(PPh_3)₂ $\text{Pt}(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CBu}^t)_2]\text{Pd}(\eta^3\text{-C}_3\text{H}_5)]^+$ ⁹ containing structural information about an η^2 -alkyne interaction to a cationic palladium center “ $\text{Pd}(\text{C}_3\text{H}_5)^+$ ”. Complex **10** represents a new example in which two $\text{C}\equiv\text{CPh}$ ligands are η^2 -coordinated to an electrophilic neutral palladium(II) center of the “ $\text{Pd}(\text{C}_6\text{F}_5)_2$ ” building block.

The palladium center is located in a slightly distorted square-planar environment formed by two $\eta^2\text{-C}\equiv\text{C}$ bonds (C(13)–C(14), C(21)–C(22)) and two $\sigma\text{-C}_6\text{F}_5$ ligands, the dihedral angle between the planes Pd–C(1)–C(7) and Pd(1)–M1–M2 (M1 and M2 are the midpoints of C(13)≡C(14) and C(21)≡C(22)) being only 6.6°. As found in the cation [*cis*-(PPh_3)₂ $\text{Pt}(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CBu}^t)_2]\text{Pd}(\eta^3\text{-C}_3\text{H}_5)]^+$,⁹ the η^2 -palladium alkynido linkages in **10** are asymmetric with the Pd–C $_{\alpha}$ distances approximately 0.15 Å shorter than the corresponding Pd–C $_{\beta}$ (Pd(1)–C(13), Pd(1)–C(21) 2.314(3), 2.283(3) Å versus Pd(1)–C(14), Pd(1)–C(22) 2.456(4), 2.433(4) Å, respectively). This asymmetry, although less pronounced than that found in the cation [*cis*-(PPh_3)₂ $\text{Pt}(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CBu}^t)_2]\text{Pd}(\eta^3\text{-C}_3\text{H}_5)]^+$ ⁹ ($\Delta \sim 0.2$ Å), contrasts with the symmetrical η^2 -linkages found in the anion [*cis*- $\text{Pt}(\text{C}_6\text{F}_5)_2(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CSiMe}_3)_2]\text{Pd}(\eta^3\text{-C}_3\text{H}_5)]^-$ ^{6c} and in the neutral dinuclear complex [*(dppe)* $\text{Pt}(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CR})_2]\text{Pt}(\text{C}_6\text{F}_5)_2$],^{6a} in which both alkynyl ligands of the neutral 3-platinapenta-1,4-diyne neutral fragment are also η^2 -coordinated to a similar $\text{M}(\text{C}_6\text{F}_5)_2$ building block. The angles formed by the $\text{C}\equiv\text{C}$ vectors and the normal to the palladium coordination plane (Pd, C(1), C(7), M1, and M2) are 48.6(2)° for C(13,14) and 46.7(2)° for C(21,22). This structural feature clearly forces the Pd center to be located out of the 3-platinapenta-1,4-diyne plane (Pt, C(13), C(14), C(21), C(22)) by 1.309(2) Å, resulting in a central bent dimetallacycle PtC_4Pd core (the dihedral angle formed by the Pd and Pt coordination planes is 58.46(6)°). A similar structural feature (type **I**, Scheme 2) has been found in other

dinuclear chelating $[M](\mu-C\equiv CR)_2M'L_n$ complexes containing $M'L_n$ building blocks with square-planar environments at M' .^{6a-d} However, this structural conformation (type **I**, Scheme 2) contrasts with that typically found in other well-known heterometallic tweezer-like complexes in which the M' center is well embedded by bis(alkynyl)titanocene fragments displaying almost planar TiC_4M' cores (type **II**, Scheme 2).¹⁴ The factors responsible for the preferred *in* or *out*- η^2 alkyne-M bonding interaction in this type of adduct are still poorly understood. For instance, the only reported examples in which a bis(alkynyl)platinum fragment forms tweezer-like adducts correspond to $[(C_6F_5)_2Pt(C\equiv CSiMe_3)_2]^-MX_2^{2-}$ ($MX_2 = HgBr_2^{15}$ and $CoCl_2^{16}$). In these anions, the preference of the chelated metal center for *in*-plane η^2 -alkyne-M bonding interactions could be ascribed to their resulting tetrahedral environments with lower steric requirements. However, in the related trinuclear anion $[(Pt(C\equiv CBut)_2)(CoCl_2)_2]^{2-}$, the η^2 -alkyne cobalt bonding interactions take place *out* of the $Pt(C\equiv C)_2$ entities¹⁶ and the bending of the central PtC_4Co cores is accompanied by a significant decrease in the Pt-Co distance (0.44 Å). It was suggested that the weak attraction between the basic platinum and acidic cobalt centers (3.007 Å) appears to drive the distortion of the PtC_4Co core from planarity and, hence, determines the final *out*-of-plane η^2 -alkyne-cobalt interactions. In complex **10**, the $Pt\cdots Pd$ distance is also rather long (3.1582(11) Å), excluding any metal-metal interaction.

As a consequence of the η^2 -coordination of the two arms of the 3-platina-1,4-diyne fragment $cis-[Pt(C\equiv CPh)_2(PPh_2C\equiv CBut)_2]$ to the palladium atom Pd(1), the following structural features arise: (i) slight bending of the $Pt-C_\alpha\equiv C_\beta-C$ units from linearity (angles at C_α 175.8(3)°/175.7(3)° and at C_β 166.2(4)°/164.5(4)°) which is comparable to those found in related systems^{6,9,14-16} and (ii) a slight decrease of the bite angle $C(13)-Pt(1)-C(21)$ (81.87(14)°) with respect to the expected value of 90°. It should be noted that this decrease (~9°) is slightly larger than those found in the tweezer-like derivatives $[(Pt(C_6F_5)_2(C\equiv CSiMe_3)_2)MX_2]$ ($MX_2 = HgBr_2$ 88.0(9)°,¹⁵ $CoCl_2$ 86.5(9)°¹⁶).

Apart from the above considerations, all other distances and angles in the organometallic platinum fragment $cis-[Pt(C\equiv CPh)_2(PPh_2C\equiv CBut)_2]$ are within the expected ranges¹⁷ (see Table 4). In particular, the $C\equiv C$ bond lengths 1.189(5), 1.177(5) Å and angles 165.7(4)°, 177.6(5)° in the phosphinoalkyne ligands are those expected for noncoordinated phosphinoalkynes,¹⁷ although the entity $P(1)-C(59)-C(60)$ (165.7(4)°) is slightly more deviated from linearity, probably due to steric effects.

The relative orientation of the two $PPh_2C\equiv CPh$ ligands is of interest. The $C(41)\equiv C(42)$ bond vector is

oriented almost perpendicular to $C(59)\equiv C(60)$ (71.9(4)°), but the linear alkynyl moieties do not cross one another. The triple bonds are rotated away from one another, and the separation between the two C_α carbon atoms is very large (3.355(5) Å). Carty *et al.* have established a relationship between the facility of intramolecular coupling of uncoordinated alkyne triple bonds in phosphinoalkynes and the proximity between the α -carbon atoms of the proximal alkyne units.^{17b} Thus, the dichloro complex $cis-[PtCl_2(PPh_2C\equiv CPh)_2]$ with the linear alkynyl moieties "crossed" and with a $C_\alpha-C_\alpha$ separation of 3.110(10) Å undergoes alkyne coupling under relatively mild conditions. However, our compound with the triple bonds rotated shows no evidence of coupling below its decomposition temperature.

The 1H , ^{19}F , and ^{31}P NMR data for dinuclear complexes **5–12** are consistent with the solid-state structure of complex **10**. Thus, 1H NMR spectra of *tert*-butylacetylide-bridged complexes (**7**, **8**, **11**, and **12**) show, besides multiplets due to the phenyl protons, a singlet at 0.78 (**7**, **8**) or 0.76 (**11**, **12**) ppm due to the equivalent But groups, which remain as singlets even at -50 °C. In addition, complexes **11** and **12** show another singlet at 0.99 (**11**) or 1.00 (**12**) ppm attributed to the But groups on the terminal $PPh_2C\equiv CBut$ units, as in complexes **9** and **10** (δ 1.03 ppm). The equivalent phosphorus atoms of the terminal phosphinoalkyne ligands in these dinuclear derivatives appear in the ^{31}P NMR spectra at systematically lower frequencies (range from δ -8.53 to -13.06) with respect to the values observed in the precursors (δ -5.87 to -7.90). The magnitude of $^1J_{Pt-P}$ (2644–2692 Hz) is slightly larger than in the corresponding mononuclear homologues with terminal $C\equiv CR$ groups (2311–2360 Hz), suggesting that the *trans* influence of a bridging alkynyl ligand is presumably smaller.

As is obvious from Figure 1, the two C_6F_5 groups in these dinuclear derivatives (**5–12**) are equivalent but the two halves of each C_6F_5 ring are inequivalent. Accordingly, room temperature ^{19}F NMR spectra of complexes with *tert*-butylacetylide bridging ligands (**7**, **8**, **11**, and **12**) display the expected five signals of equal intensity, thus indicating a rigid structure on the NMR time scale. In contrast, the NMR spectra of complexes **5**, **6**, **9**, and **10** with phenylacetylide bridging ligands show only three signals of relative intensity 2:1:2, evidencing that the two halves of each C_6F_5 ring appear equivalent at room temperature and indicating that these complexes are not rigid in solution. By lowering the temperature (-50 °C), five distinct fluorine resonances are clearly resolved for the diplatinum derivatives only (**5**, **9**). When the heterobinuclear derivatives $[L_2Pt(\mu-C\equiv CPh)Pd(C_6F_5)_2]$ **6** ($L = PPh_2C\equiv CPh$) and **10** ($L = PPh_2C\equiv CBut$) are cooled, their spectra remain unchanged indicating equivalence of the *endo* and *exo* *o*-F atoms (and *m*-F atoms as well) even at low temperature (-50 °C). This equivalence can be achieved by either of the two following processes: (i) free rotation of the C_6F_5 groups about the M-C linkages or (ii) fast exchange of the $M(C_6F_5)_2$ unit below and above the 3-platina-1,4-diyne fragments $L_2Pt(C\equiv CPh)_2$. Although the first possibility has been previously noted as severely sterically hindered in square-planar derivatives,¹⁸ it has been proposed in several systems¹⁹ and could be accessible *via* tricoordinate species through the cleavage

of one of the M–alkyne bonds.²⁰ The second possibility, previously suggested by us in the related complexes $[\text{L}_2\text{Pt}(\mu\text{-C}\equiv\text{CR})_2\text{Pt}(\text{C}_6\text{F}_5)_2]$ ($\text{L} = \text{PPh}_3$, dppe, COD),^{6a} implies a formal inversion of the central PtC_4M ($\text{M} = \text{Pd}$, Pt) cores. This inversion could take place *via* intermediate species with one or both alkynyl ligands symmetrically bridging the two metal centers.²¹ The results indicate that this process is less favorable for the *tert*-butylalkynide-bridged complexes than for phenyl compounds because of the lower total energy required by the phenyl complexes to reach the transition state which is stabilized by the phenyl π electrons. Notwithstanding, in these derivatives, exchange mechanisms that entail $\text{PPh}_2\text{C}\equiv\text{CR}$ participation cannot be excluded either.

The very low stability of the mixed Pt–Pd derivatives (**6**, **8**, **10**, and **12**) in solution prevented their characterization by ^{13}C NMR spectroscopy. This was, however, possible for the diplatinum **5**, **7**, **9**, and **11** compounds (see Experimental Section and Table 3). The most noticeable observation is that upon η^2 -coordination of the alkynyl ligands to the platinum atoms, the resonances of both C_α and C_β carbon atoms moves slightly upfield. A similar upfield shift of alkynyl carbon signals has been previously observed in the formation of dimeric $[\text{X}_2\text{Pt}(\mu\text{-C}\equiv\text{CR})_2\text{Pd}(\text{C}_6\text{H}_5)]^-$ ($\text{X} = \text{C}_6\text{F}_5$, $\text{C}\equiv\text{CR}$)⁹ complexes containing alkynyl bridging ligands. It should be noted that this result contrasts with previous observations, showing that η^2 -complexation of terminal alkynyl ligands to a second metal center results in a downfield shift of these signals.^{14d,22} On the other hand, although the alkyne carbon resonances of the phosphinoalkyne ligands are less affected in the formation of these dimeric complexes, the $\text{P}-\text{C}_\alpha\equiv$ carbon signals are also slightly shifted upfield while the $\equiv\text{C}_\beta-\text{R}$ signals move downfield. In addition, the values of the $^1J_{\text{P}-\text{C}_\alpha}$ coupling constants are slightly larger in these complexes (109–115 Hz) than those observed in the precursors **1–4** (98.2–105.5 Hz) (see Table 3). It should be noted that in complexes **7** and **11**, the signals due to the phenyl rings of the $\text{PPh}_2\text{C}\equiv\text{CR}$ ligands are observed to be magnetically inequivalent, probably because of the hindered rotation across the Pt–P bonds.

Trinuclear Derivatives. In order to force the coordination of the *P*-bonded phosphinoalkyne ligands, the reactions of the mononuclear complexes **1–4** with 2 equiv of $\text{cis-}[\text{M}(\text{C}_6\text{F}_5)_2(\text{thf})_2]$ ($\text{M} = \text{Pt}$, Pd) were also explored. The results, summarized in Scheme 3, clearly indicate that the course of the reactions and the final products strongly depend on the alkynyl substituents, both in the alkynido and phosphinoalkyne ligands and in the metal centers.

The *tert*-butylacetylide complexes $\text{cis-}[\text{Pt}(\text{C}\equiv\text{CBu}^t)_2\text{L}_2]$ ($\text{L} = \text{PPh}_2\text{C}\equiv\text{CPh}$ (**2**), $\text{PPh}_2\text{C}\equiv\text{CBu}^t$ (**4**)) react with 2.2 equiv of $\text{cis-}[\text{Pt}(\text{C}_6\text{F}_5)_2(\text{thf})_2]$ to give the desired trinuclear derivatives **15A** and **18A**, respectively, in moderate yield (see Experimental Section). In these complexes (type **A**), the mononuclear precursors (**2**, **4**) act as symmetrical bis($\text{cis-}\eta^2\text{:}\kappa(\text{P})\text{:}\eta^2$) chelating tetradentate ligands. Therefore, the complexed $\text{cis-Pt}(\text{C}_6\text{F}_5)_2$ units are linked to the central platinum atom through both a *tert*-butylalkynyl fragment ($\mu\text{-}\eta^2\text{-C}\equiv\text{CBu}^t$) and a diphenylalkynylphosphine bridging ligand ($\mu\text{-}\kappa(\text{P})\text{:}\eta^2$), as established by an X-ray diffraction study on complex **15A** (*vide infra*). NMR (^{31}P and ^{19}F) monitoring of both reactions clearly indicates that the formation of complexes **15A** and **18A** takes place *via* the corresponding dinuclear derivatives **7** and **11**, respectively. Initially (within seconds), the formation of **15A/7** and **18A/11** mixtures in ratios of 80:20 and $\sim 10:90$, respectively, were observed (see Scheme 3). The gradual disappearance of **7** and concomitant formation of **15A** is clean and takes place completely in ~ 1 h. However, the evolution of the reaction system $4/\text{cis-}[\text{Pt}(\text{C}_6\text{F}_5)_2(\text{thf})_2]$ is more complicated due to the much slower formation of **18A** and to its low stability in solution; it reverts to the dinuclear derivative. The greatest amount of **18A** in solution is reached after 3 h (**18A/11** ratio $\approx 83:11$), and with longer reaction times, the concentration of **18A** decreases while that of **11** increases (a 55/45 ratio after 7 h). The formation of **15A** and **18A** through the corresponding dinuclear derivatives requires a reorganization of the bonded $\text{cis-Pt}(\text{C}_6\text{F}_5)_2$ unit and a significant reorientation of both phosphinoalkyne groups. It seems likely that this latter process should be somewhat more difficult with the bulkier $\text{PPh}_2\text{C}\equiv\text{CBu}^t$ groups, thus explaining the observed slower reaction rate for complex **18A**. Attempts to prepare the PtPd_2 analogues of **15A** and **18A** failed. When 2 equiv of $\text{cis-}[\text{Pd}(\text{C}_6\text{F}_5)_2(\text{thf})_2]$ is reacted with the mononuclear *tert*-butylalkynido derivatives **2** and **4** in dichloromethane, very dark brown solutions are formed from which only the dinuclear complexes **8** and **12**, respectively, can be isolated. In the case of the reaction between **4** and $\text{cis-}[\text{Pd}(\text{C}_6\text{F}_5)_2(\text{thf})_2]$, the NMR spectra in CDCl_3 of the reaction mixture reveals that the dinuclear complex **12** is the only phosphorus-containing platinum species present in solution. The ^{19}F NMR spectrum confirms the presence of excess $\text{cis-Pd}(\text{C}_6\text{F}_5)_2(\text{thf})_2$ and shows the formation of considerable amounts of decafluorobiphenyl ($\text{C}_6\text{F}_5-\text{C}_6\text{F}_5$). If the $\text{C}_6\text{F}_5-\text{C}_6\text{F}_5$ formed comes from a possible trinuclear coordination complex, it has a lifetime that is too short to allow observation by NMR spectroscopy. NMR examination of the crude product of the reaction mixture between **2** and $\text{cis-}[\text{Pd}(\text{C}_6\text{F}_5)_2(\text{thf})_2]$ reveals that, at low temperature (-50°C), the dinuclear complex **8** is formed almost instantaneously and an excess of $\text{cis-}[\text{Pd}(\text{C}_6\text{F}_5)_2(\text{thf})_2]$ is the only other solute present. When the temperature was increased to room temperature, considerable decomposition takes place (Pd , $\text{C}_6\text{F}_5-\text{C}_6\text{F}_5$) together with concomitant formation of other new unidentified platinum phosphine complexes (^{31}P NMR $\delta(\text{P})$ 37.6 (d), 33.8 (m), 31.4 (d), 27.5 (d)). Unfortunately, the low relative amounts of these species and the very low stability of the reaction mixture at room temperature precluded their identification.

Scheme 3

As shown in Scheme 3 (see Experimental Section), similar reactions of 2 equiv of *cis*-[Pd(C₆F₅)₂(thf)₂] with the *cis*-bis(phenylacetylide)bis((diphenylphosphino)alkyne) platinum complexes **1** and **3** in CH₂Cl₂ instantaneously yield a new type of triangular PtPd₂ complexes (**14B** and **17B**) together with small amounts of the corresponding dinuclear derivatives **6** (traces, less than 5%) and **10** (~20%), respectively, as proven by NMR spectroscopy (³¹P and ¹⁹F). Crystallization of the crude mixture at low temperature (CH₂Cl₂/hexane interface) gave a pure sample of **17B**. Both derivatives are stable at low temperature (~-30 °C) as solids but rapidly decompose in CDCl₃ at room temperature (~12 h) to the corresponding dinuclear derivatives, depositing Pd metal and giving, probably through a reductive elimination process, a considerable amount of C₆F₅-C₆F₅. An analogous reaction between complex **3** (L = PPh₂C≡CBu^t) and 2 equiv of *cis*-[Pt(C₆F₅)₂(thf)₂] also gives a similar mixture of **9** and the new triangular Pt₃ complex **16B** instantaneously, which is an isomer of **15A**, in an approximate 15:85 mixture from which pure **16B** can be isolated as a white microcrystalline solid in high yield (45%) after work-up. The structure of complex **16B**, which is stable both as a solid and in solution (CDCl₃) has been determined by X-ray crystallography, confirming that in this case the PPh₂C≡CBu^t groups act as terminal ligands and both phenylethy-

nylalkyl fragments behave as six-electron donors (μ_3 - η^2 , σ, π, π). Finally, the reaction between **1** (L = PPh₂C≡CPh) and 2 equiv of *cis*-[Pt(C₆F₅)₂(thf)₂] is less selective, giving both isomers **13A** and **13B** in a 50:32 ratio and ~80% conversion (dinuclear complex **5**, ~18%, is also present) after a reaction time of 2 h. Interestingly, NMR (³¹P and ¹⁹F) examination of this reaction shows (Scheme 3) an initial **13A**:**13B**:**5** mixture in a 50:10:40 ratio. After 2 h, the signals assigned to complex **5** clearly have diminished while the proportion of **13B** has increased significantly. No detectable change was observed after 8 h, with the final ratio being ~50:32:18 as mentioned above. Several attempts to separate at least the dominant component (**13A**) were unsuccessful; therefore, both derivatives have been characterized spectroscopically only on the basis of their NMR properties (mainly ³¹P), which are similar to these of the rest of the complexes.

Both types of trinuclear complexes (**A** and **B**) display very characteristic spectroscopic data consistent with the corresponding formulation shown in Scheme 3 and in agreement with the structures of **15A** and **16B** presented in Figures 2 and 3, respectively. Thus, in the IR spectra of complexes **15A** and **18A**, there are only characteristic absorptions (see Table 1) in the expected range for complexed carbon-carbon triple bonds,^{6,9,14,19a,22} thus confirming that all acetylene fragments are in-

Figure 2. Drawing of the molecular structure of $[\{\text{Pt}(\mu\text{-}\kappa(\text{P})\text{:}\eta^2\text{-PPh}_2\text{C}\equiv\text{CPh})_2(\mu\text{-}\eta^1\text{:}\eta^2\text{-C}\equiv\text{CBu}^1)_2\}\{\text{Pt}(\text{C}_6\text{F}_5)_2\}_2]$, **15A**.

Figure 3. Molecular structure of $[\{(\text{PPh}_2\text{C}\equiv\text{CBu}^1)_2\text{Pt}(\mu_3\text{-}\eta^2\text{-C}\equiv\text{CPh})_2\}\{\text{Pt}(\text{C}_6\text{F}_5)_2\}_2]$, **16B**.

involved in side-on coordination. In contrast, the IR spectra of complexes **14B**, **17B** (PtPd_2), and **16B** (PtPt_2) show two strong $\nu(\text{C}\equiv\text{C})$ absorptions in the range 2151–2210 cm^{-1} , indicating the presence of a terminal phosphinoalkyne ligand. All three complexes exhibit additional weak $\nu(\text{C}\equiv\text{C})$ bands at lower frequencies (1951 cm^{-1} (**14B**), 1883, 1870 (sh) (**16B**), and 1951 cm^{-1} (**17B**)), evidencing the presence of bridging alkynyl ligands. It should be noted that in accord with the behavior of alkynyl groups as six-electron donors, this shift to lower frequencies (cf $\nu(\text{C}\equiv\text{C})$ at 2124 and 2117 cm^{-1} in **1** and **3**, respectively) is significantly more pronounced than that observed for the dinuclear complexes in which $\nu(\text{C}\equiv\text{C})$ can be observed (range 2068–2040 cm^{-1} ; 1951 cm^{-1} in **14B** vs 2068 cm^{-1} in **6**).

Characteristic of the presence of (diphenylphosphino)alkyne bridging ligands in complexes of type **A** is a considerable downfield shift of the ^{31}P ($\delta(\text{P})$) resonance ($\delta(\text{P})$ -0.92 (**15A**), -1.96 (**18A**), and 0.67 (**13A**)) with respect to that observed in the mononuclear precursors (-6.13 (**2**), -7.76 (**4**), -5.87 (**1**)) or in the corresponding dinuclear derivatives in which the $\text{PPh}_2\text{C}\equiv\text{CR}$ molecules act only as *P*-donor ligands (-10.56 (**7**), -13.06 (**11**), -10.4 (**5**)). This spectroscopic fact can be attributed to the characteristic formation of (both) dimetallacycles in which the $\text{PPh}_2\text{C}\equiv\text{CR}$ ligands are involved as bridging ligands. However, the platinum–phosphorus coupling constants (2488 (**15A**), 2501 (**18A**), 2524 Hz (**13A**)) are less affected, being slightly larger than those observed for the starting precursors (2311 (**2**), 2335 (**4**), 2343 Hz (**1**)) but slightly smaller than those seen for the dinuclear complexes (2674 (**7**), 2689 (**11**), 2679 Hz (**5**)).

In contrast, the equivalent phosphorus atoms of the terminal phosphinoalkyne moieties in complexes of type **B** appear in the ^{31}P NMR spectra as singlets clearly shifted to lower frequencies ($\delta(\text{P})$ -19.5 (**13B**), -14.10 (**14B**), -20.55 (**16B**), -14.80 (**17B**)) with respect to the values observed in the precursors (-5.87 (**1**), -7.90 (**3**)) and in the corresponding dinuclear derivatives (range -8.53 (**6**) to -12.79 (**9**)). Moreover, all $^1J_{\text{Pt-P}}$ coupling constants are extraordinarily large (range from 2891 Hz for **14B** to 3008 Hz for **16B**) compared to the range observed for either mononuclear and dinuclear complexes (see Table 2). This points to a weaker σ -interaction between Pt(1) and the C_α carbon atoms of the alkynyl ligands due to their additional interaction with the remaining two platinum centers (σ -Pt(1), π -Pt(2), π -Pt(3)) which seem to be compensated by stronger interactions with the *P*-bonded phosphinoalkyne ligands. Unfortunately, the ^{13}C NMR spectrum of complex **16B** is not informative (see Experimental Section and Table 3) since the Pt– $\text{C}_\alpha\equiv$ carbon resonances could not be located in spite of prolonged accumulation. The spectra of **14B** and **17B** could not be obtained due to their very low stability in solution.

The ^{19}F NMR spectra of both types of complexes (**A** and **B**) are temperature dependent (see Table 2). For instance, at low temperature (-50°C), complex **15A** displays two different sets of five fluorine signals (two F_o , F_p , and two F_m), in keeping with the presence of two inequivalent rigid C_6F_5 groups in which both halves of each ring are inequivalent (AFMRX system). When the temperature is increased, the two *ortho* and two *meta* fluorine resonances of one of the sets clearly broaden and, finally, collapse to only two broad signals at room temperature ($\sim 288\text{ K}$) giving a $\Delta G^\ddagger(T_c)$ value of approximately 53 KJ/mol for the process that renders the *o*-F resonances equivalent.²³ The remaining five signals due to one of the C_6F_5 rings appear sharp at this temperature (room temperature). The spectra can be tentatively explained by assuming that the presence of different ligands *trans* to the C_6F_5 rings (alkynyl and phosphinoalkyne) induces different energy barriers on their rotation around the Pt– $\text{C}_{\text{ipso}}(\text{C}_6\text{F}_5)$ bonds. Thus, at low temperature the rotation seems to be stopped for both rings, but at higher temperatures this process is faster for one of them, averaging the two F_o (and the two F_m) resonances. A similar behavior has been found previously in other complexes containing the *cis*-Pt–

(C₆F₅)₂CO fragment, which also has different ligands *trans* to the pentafluorophenyl groups.^{19a,b} The behavior of **18A** is not clear (see Table 2 for data), as the two sharp *F_p* triplets observed at room temperature, in accord with the two expected types of C₆F₅ rings, also broaden when the temperature is lowered. At –50 °C, two sets of two overlapping triplets are seen, suggesting that at low temperature the complex is rigid and all C₆F₅ groups are inequivalent.

Similarly, in agreement with the behavior of the phenylacetylide precursors **1** and **3** as chelating tetradentate bridging ligands binding through the alkynyl groups to both *cis*-M(C₆F₅)₂ units, the ¹⁹F NMR spectra of **14B**, **17B**, and **16B** at room temperature exhibit a single set of three signals (2:1:2; 2*F_o*, *F_p*, 2*F_m*) evidencing that all C₆F₅ groups are equivalent. The resonances assignable to *F_o* and *F_m* are very broad, also suggesting the existence of a dynamic process. On lowering the temperature, splitting occurs and the expected pattern corresponding to an AFMRX system is observed for all complexes at –50 °C. Using the coalescence temperatures given in Table 2 and the chemical shift difference on *F_o* at 223 K, Δ*G*[‡] (*T_c*) values of 52.1 (**14B**), 47.6 (**16B**), and 51.9 (**17B**) KJ/mol are obtained.²³ The spectrum of complex **17B** remains unaffected in the presence of an excess of *cis*-[Pt(C₆F₅)₂(thf)₂], suggesting an intramolecular exchange process.

Crystal Structures of [(Pt(μ-κ(P):η²-PPh₂C≡CPh)₂-(μ-η¹:η²-C≡CBu^t)₂]{Pt(C₆F₅)₂}] (15A·0.5C₆H₁₄·0.45C₆H₆) and [(PPh₂C≡CBu^t)₂Pt(μ₃-η²-C≡CPh)₂]-{Pt(C₆F₅)₂}] (16B). The structure of the trinuclear complex **15A** is presented in Figure 2 together with the atom-labeling scheme used. Selected bond distances and angles are collected in Table 5. As shown, the most remarkable feature is that both terminal *cis*-Pt(C₆F₅)₂ moieties are linked to the central platinum atom through both an alkynyl unit (μ-η²) and a phosphinoalkyne ligand (μ-κ(P):η²). To the best of our knowledge, this is the first organometallic species possessing such a structure.

The platinum atoms have basically square-planar geometries, but their coordination environments are

different. The central Pt(2) atom is bound to the C_α atoms of the two C≡CBu^t groups, which are mutually *cis*, and to the two P atoms of the two PPh₂C≡CPh ligands. The alkyne entities (C≡CBu^t and PPh₂C≡CPh) are each η²-coordinated to both terminal Pt(1) and Pt(3) atoms, which complete their coordination environment with the C_{ipso} atoms of the two C₆F₅ groups, also mutually *cis*. This structural disposition indicates that again the reaction between complex **2** and 2 equiv of *cis*-[Pt(C₆F₅)₂(thf)₂] proceeds with retention of the original configuration about the platinum centers. It should be noted, however, that the formation of complex **15A** through the dinuclear derivative **7** as an intermediate (complex **15A** is also formed starting from **7** and 1 equiv of *cis*-[Pt(C₆F₅)₂(thf)₂]) requires at least a minor movement of the initial *cis*-Pt(C₆F₅)₂ unit bonded.

Both terminal platinum atoms Pt(1) and Pt(3) are held in the complex by almost symmetrical π-bonding interactions to the carbon–carbon triple bonds (the most asymmetric interaction is found with the P–C(57)≡C(58)–Ph acetylenic fragment Pt(3)–C(57) 2.179(8) Å; Pt(3)–C(58) 2.294(8) Å) with typical Pt(1,3)–C_{α,β} distances (2.179(8)–2.322(8) Å).⁶ The C–C alkyne distances at the acetylenic carbons of the PPh₂C≡CPh ligands (1.233(11), 1.226(11) Å) are similar to the corresponding ones involving the C≡CBu^t alkynyl groups (1.220(1), 1.211(11) Å) but, as expected, longer than those observed for complexes **10** (average 1.183(5) Å) and **16B** (average 1.184(13) Å) which have terminal PPh₂C≡CBu^t ligands. These distances are within the typical range of an alkyne bonded to transition metals that do not strongly back-bond.^{4,6,15,16,19a} The acetylenic skeletons are slightly distorted from linearity, with the bend at the C_α carbon atoms more pronounced on the P–C_α–C_β–Ph entities (P–C_α–C_β 154.6(7)°, 160.9(7)° vs Pt–C_α–C_β 166.5(7)°, 172.7(7)°). The angles at the C_β carbon atoms are 162.1(8)° and 153.9(8)° on the Pt–C_α–C_β–C(Bu^t) entities and 160.5(8)°, 160.6(8)° at the P–C_α–C_β–C(Ph) fragments. The difference in the values of the platinum coupling constants between the dinuclear and trinuclear derivatives (**A** and **B**) is not reflected in the platinum–phosphorus bond lengths, which are identical within experimental error (mean values 2.277(2) (**15A**), 2.271(10) (**10**), 2.276(2) Å (**16B**)). As expected, the compound is not planar. The dihedral angles between the best least-squares coordination planes of each platinum center are Pt(1) plane–Pt(2) plane = 82.9°, Pt(2) plane–Pt(3) plane = 80.35°, and Pt(1) plane–Pt(3) plane = 68.13°. The observed Pt(2)–Pt(1,3) separations (3.560(1) and 3.597(1) Å) exclude the possibility of metal–metal bonding.

A perspective drawing of the structure of complex **16B** is depicted in Figure 3 together with the atom-numbering scheme. A summary of the important bond distances and angles is given in Table 6. As shown, in this complex the precursor fragment **3** acts a chelating tetradentate ligand bound through the alkynyl groups, giving a triangular Pt₃ core with intermetallic angles close to 60°. The Pt₃ plane is bicapped by two triply bridging phenylacetylide groups which are bonded in a μ₃-η² (σ,2π) fashion. Thus, both alkynyl ligands remain σ-bonded to Pt(1) (Pt(1)–C(1,9) 2.013(9), 2.001(9) Å) and are π-bonded to Pt(2) and Pt(3) with platinum–carbon distances in the range 2.266(9)–2.408(9) Å. It is interesting to note that these distances and the C_α

C(10)–C(9)–Pt(3)	75.3(5)	C(9)–C(10)–C(11)	150.9(9)
C(9)–C(10)–Pt(3)	73.0(6)	C(9)–C(10)–Pt(2)	71.4(5)
Pt(3)–C(10)–Pt(2)	81.5(3)	C(18)–C(17)–P(1)	170.2(9)
C(17)–C(18)–C(19)	178.6(10)	C(35)–C(36)–C(37)	176.6(11)
C(36)–C(35)–P(2)	175.6(10)		

(168.9(7)°, 163.4(8)°) and C_β (150.9(9)°, 152.5(9)°) bending of the alkynyl ligands are comparable to the parameters found in [(dppe)Pt(μ - η^2 -C≡CPh)₂Pt(C₆F₅)₂] (Pt(2)–C 2.269(13)–2.345(12) Å; angles at C_α 167.2°/159.2° and at C_β 164.6°/156.2°) in which the 3-platinal-1,4-alkyne fragment chelates only one Pt(C₆F₅)₂ fragment.^{6a} However, the carbon–carbon triple bond distances are, as expected, slightly longer (1.270(12), 1.263(11) Å in **16B** vs 1.229(17), 1.234(16) Å in the dinuclear derivative),^{6a} and the bite angle C(1)–Pt(1)–C(9) of 76.2(3)° is only slightly smaller than that found in [(dppe)Pt(μ - η^2 -C≡CPh)Pt(C₆F₅)₂] (79.3(4)°).

The platinum–platinum distances (Pt(1)–Pt(2,3) 3.2219(5), 3.1973(5) Å and Pt(2)–Pt(3) 3.0982(5) Å) are consistent with nonbonding interactions. As expected, the geometry around the platinum atoms is approximately square planar. An interesting structural feature is that, probably due to the presence of two Pt(C₆F₅)₂ units above and below the Pt(1) coordination plane, the chelating platinadiyne fragment [Pt(1)C(1)C(9)C(2)C(10)] is nearly planar (max deviation 0.020 Å for C(9)) with the phenyl substituents of the alkynyl ligands also lying in the same plane. The dihedral angles between these phenyl groups and the above platinadiyne plane are 38.0° and 36.5°, respectively.

The reasons for the final formation of these triangular molecules only with the phenylacetylide **1** and **3** precursors are difficult to discern, but the steric effects of the bulky *tert*-butylacetylide ligands cannot be discarded. Although several systems with two bridging alkynyl ligands have been reported so far [Os₃(CO)₇(μ - η^2 -C≡CPr)₂-(μ -PPh₂)₂],^{24a} [Os₃(μ - η^1 -C₂R)(μ_3 - η^2 -C₂R)(CO)₉],^{24b,c} [Ru₃(μ -

η^1 -C₂Bu^t)(μ - η^2 -C₂Bu^t)(PPh₂)₂(CO)₅(PPh₂Bu^t)],²⁵ [Cu₃(μ_3 - η^1 -C≡CPh)₂(μ -dppm)₃](BF₄)₂,²⁶ and [PtAg₂(C₆F₅)₂(μ - η^2 -C≡CR)(μ_3 - η^1 -C≡CR)(PPh₃)₂],²⁷ to our knowledge the triangular Pt₃ core bicapped by two (μ - η^2 -C≡CPh) ligands observed for **16B** is unprecedented.

Conclusion

The coordination ability of *cis*-bis(alkynyl)bis((diphenylphosphino)alkyne)platinum(II) complexes toward *cis*-[M(C₆F₅)₂(thf)₂] (M = Pt, Pd) has been studied. From this study, it is clear that the alkynyl (C≡CR) is the preferred bridging ligand. Thus, exclusive formation of double alkynyl bridging systems takes place in the formation of all 1:1 adducts (**5**–**12**). In addition, complexation *via* phenylethynyl fragments seems to predominate in the formation of trinuclear derivatives, as deduced from the following results: (i) complexation of the second *cis*-Pd(C₆F₅)₂ unit is only straightforward with the phenylethynyl substrates *cis*-[Pt(C≡CPh)₂L₂] (**1** and **3**) and takes place *via* C≡CPh groups which act as μ_3 - η^2 bridging ligands; and (ii) while *cis*-[Pt(C≡CPh)₂-(PPh₂C≡CBu^t)₂] (**3**) binds both *cis*-Pt(C₆F₅)₂ units through a double alkynyl bridging system (μ_3 - η^2 -C≡CPh)₂, **16B**, *cis*-[Pt(C≡CBu^t)₂(PPh₂C≡CPh)₂] (**2**) forms the isomeric symmetrical adduct [{Pt(μ - κ (P): η^2 -PPh₂C≡CPh)₂(μ - η^1 : η^2 -C≡CBu^t)₂}{Pt(C₆F₅)₂}]₂, **15A**, containing PPh₂C≡CPh bridging ligands. These results establish the order of bonding capability as follows: alkynyl > *P*-bonded phosphinoalkyne and C≡CPh units > C≡CBu^t units. Finally, the formation of complexes **15A** and **18A** clearly shows that the preference for η^2 -alkyne–metal interactions is higher in platinum than in palladium substrates.

Experimental Section

General Methods. All reactions were carried out under N₂ using dried solvents purified by known procedures and distilled prior to use. IR spectra were recorded on a Perkin-Elmer 883 spectrometer from Nujol mulls between polyethylene sheets. NMR spectra were recorded on a Varian Unity 300 and a Bruker ARX 300 spectrometer. Chemical shifts are reported in ppm relative to external standards (SiMe₄, CFCl₃, and 85% H₃PO₄). Elemental analyses were carried out with a Perkin-Elmer 240-B microanalyzer and the mass spectra (FAB⁺) on a VG Autospec spectrometer. [PPh₂C≡CPh],²⁸ [PPh₂C≡CBu^t],²⁸ [Pt(C≡CPh)₂COD],²⁹ [Pt(C≡CBu^t)₂COD],^{6a} and *cis*-[Pt(C₆F₅)₂(thf)₂]³⁰ were prepared by published procedures.

Synthesis of *cis*-[Pt(C≡CR)₂L₂] (L = L¹ = PPh₂C≡CPh, R = Ph (1**), Bu^t (**2**); L = L² = PPh₂C≡CBu^t, R = Ph (**3**), Bu^t (**4**)).** A typical preparation (complex **1**) was as follows: To a suspension of [Pt(C≡CPh)₂COD] (0.200 g, 0.396 mmol) in CH₂Cl₂ (10 cm³) was added PPh₂C≡CPh (0.226 g, 0.791 mmol), immediately giving an orange solution. After the mixture was stirred for 10 min, the resulting solution was

Synthesis of [(L₂Pt(μ-η¹:η²-C≡CR)₂)(M(C₆F₅)₂)] (L = L¹ = PPh₂C≡CPh, R = Ph, M = Pt (5**), Pd (**6**); R = Bu^t, M = Pt (**7**), Pd (**8**); L = L² = PPh₂C≡CBu^t; R = Ph, M = Pt (**9**), Pd (**10**); R = Bu^t, M = Pt (**11**), Pd (**12**)).** **Synthesis of 5.** To a solution of cis-[Pt(C≡CPh)₂(PPh₂C≡CPh)₂] (0.140 g, 0.144 mmol) in CH₂Cl₂ (20 cm³) was added cis-[Pt(C₆F₅)₂(thf)₂] (0.097 g, 0.144 mmol), and the mixture was stirred at room temperature for 15 min. The resulting solution was concentrated to small volume (2 cm³). Addition of *n*-hexane (3 cm³) and standing at -30 °C gave **5** as a white crystalline product. Complexes **6–12** were prepared similarly using the appropriate starting materials.

[(PhC≡CPh₂P)₂Pt(μ-η¹:η²-C≡CPh)₂](Pt(C₆F₅)₂) (5**)** ¹³C NMR (CDCl₃, 16 °C): 147.8, 144.8, 137.7, 134.5 (br, C₆F₅), 132.9 (t, *J*_{CP} = 6.6 Hz, C_o, PPh₂), 131.96 (s, Ph), 131.9 (s, Ph), 130.98 (s, Ph), 130.2 (AXX' five line pattern, ¹*J*_{CP} + ³*J*_{CP} = 69 Hz, C_i, PPh₂), 130.1 (s, C_p, Ph), 128.4 (t, *J*_{CP} = 6.1 Hz, C_m, PPh₂), 127.9 (s, C_m, Ph), 127.8 (s, C_p, Ph), 126.9 (s, C_m, Ph), 124.2 (s, C_i, Ph), 119.8 (s, C_i, Ph), 109.3 (AXX', ²*J*_{CP} + ⁴*J*_{CP} = 17.3 Hz, C_β, P-C≡CPh), 103.8 (AXX', five line pattern ³*J*_{C-Ptrans} + ³*J*_{C-Pcis} = 30.5 Hz, C_β, -C_α≡C_βPh), 90.5 (dd, ²*J*_{C-Ptrans} = 145.5 Hz, ²*J*_{C-Pcis} = 19.8 Hz, C_α, -C_α≡C_βPh), 78.7 (d, ¹*J*_{CP} = 112 Hz, C_α, -PC_α≡C_βPh).

[(PhC≡CPh₂P)₂Pt(μ-η¹:η²-C≡CBu^t)₂](Pt(C₆F₅)₂) (7**)** ¹³C NMR (CDCl₃, 16 °C): 148.1 (m), 145.1 (m), 137.8 (m), 134.6 (m) (br, C₆F₅), 133.0 (m, overlapping of two triplets, C_o, PPh₂), 131.8 (s, C_o, Ph), 131.2 (AXX', ¹*J*_{CP} + ³*J*_{CP} = 45.7 Hz, C_i, PPh₂), ~130.3 (C_i, PPh₂), 130.8 (s, C_p, PPh₂), 130.6 (s, C_p, PPh₂), 129.8 (s, C_p, Ph), 128.1 (m, overlapping of two triplets, C_m, PPh₂), 127.8 (s, C_m, Ph), 120.1 (s, C_i, Ph), 113.9 (m, C_β, C_α≡C_βBu^t, Pt satellites are not observed), 108.6 (m, C_β, P-C_α≡C_βPh), ~83.2 (C_α, -C_α≡C_βBu^t), 79.5 (d, *J*_{CP} = 109 Hz, C_α, -PC_α≡C_βPh), 30.7 (s, -C(CH₃)₃), 30.1 (s, CMe₃).

[(Bu^tC≡CPh₂P)₂Pt(μ-η¹:η²-C≡CPh)₂](Pt(C₆F₅)₂) (9**)** ¹³C NMR (CDCl₃, 16 °C): 147.8 (m), 144.9 (m), 137.6 (m), 134.4 (m, br, C₆F₅), 132.9 (t, *J*_{CP} = 6.6 Hz, C_o, PPh₂), 131.9 (s, Ph), 131.6 (AXX' five line pattern, ¹*J*_{CP} + ³*J*_{CP} = 69 Hz, C_i, PPh₂), 130.8 (s, C_p, PPh₂), 128.2 (t, *J*_{CP} = 6 Hz, C_m, PPh₂), 127.7 (s, C_p, Ph), 126.9 (s, C_m, Ph), 124.3 (s, C_i, Ph), 120.0 (m, C_β, -PC_α≡C_βBu^t), 103.2 (m, ³*J*_{C-Ptrans} + ³*J*_{C-Pcis} = 30.6 Hz, C_β, -C_α≡C_βPh), 91.3 (dm, ²*J*_{C-Ptrans} ≈ 145 Hz, C_α, -C_α≡C_βPh), 68.7 (d, ¹*J*_{CP} = 115 Hz, C_α, -PC_α≡C_βBu^t), 29.5 (s, -C(CH₃)₃), 28.3 (s, CMe₃).

[(Bu^tC≡CPh₂P)₂Pt(μ-η¹:η²-C≡CBu^t)₂](Pt(C₆F₅)₂) (11**)** ¹³C NMR (CDCl₃, 16 °C): 133.1 (C_o), 133.02 (C_o) (overlapping of two triplets PPh₂), 132.20 (C_i), 132.17 (C_i) (overlapping of two AXX' fine line patterns), 130.5 (s, C_p, PPh₂), 127.97 (C_m), 127.85 (C_m) (overlapping of two triplets PPh₂), 119.2 (t, *J*_{CP} = 7.6 Hz, C_β, PC_α≡C_βBu^t), 113.3 (AXX', ³*J*_{C-Ptrans} + ³*J*_{C-Pcis} = 29.4 Hz, Pt satellites are not observed, C_β, -C_α≡C_βBu^t), 84.1 (dd, ²*J*_{C-Ptrans} = 145.9 Hz, ²*J*_{C-Pcis} = 20.5 Hz, C_α, C_α≡C_βBu^t), 69.4 (d, *J*_{CP} = 112 Hz, C_α, -PC_α≡C_βBu^t), 30.7 (s, -CH₃), 30.08 (s, CMe₃), 29.5 (s, -CH₃), 29.2 (s, CMe₃).

Reaction of cis-[Pt(C≡CPh)₂L¹]₂ (1**) with cis-[Pt(C₆F₅)₂(thf)₂]₂ (Molar Ratio of 1:2).** A mixture of cis-[Pt(C₆F₅)₂(thf)₂]₂ (0.015 g, 0.022 mmol) and cis-[Pt(C≡CPh)₂(PPh₂C≡CPh)₂]₂ (0.0108 g, 0.011 mmol) was dissolved in 0.6 cm³ of CDCl₃, and the reaction was immediately monitored by NMR spectroscopy. Integration of the NMR signals shows an approximate 50:10:40 proportion of **13A**, **13B**, and **5** (Scheme 3). After 2 h, the intensity of the signal due to the dinuclear derivative **5** decreases while the signal attributed to **13** increases with the final proportion being **13A**:**13B**:**5** 50:32:18. An identical ratio was observed after 8 h.

All attempts to separate **13A** or **13B** from this reaction mixture were unsuccessful; thus, the complexes **13A** and **13B** were only characterized by spectroscopy: ¹H NMR (CDCl₃, ppm) δ 8.00–6.8 (m, **13A** + **13B**); ¹⁹F NMR (CDCl₃, ppm) -116.5 (br), -117.2 (s, br) (F_o, **13A** + **13B**), -160.97 (t), -161.1 (t), -161.5 (t) (3F_p: 2 inequivalent F_p from **13A** and 1 F_p from **13B**), -164.1 (m), -164.6 (m) (F_m, **13A** + **13B**); ³¹P{¹H} NMR (CDCl₃, ppm) 0.67 (s, ¹*J*_{Pt-P} = 2524 Hz, **13A**), -19.5 (s, ¹*J*_{Pt-P} = 2996 Hz, **13B**). The signal due to complex **5** (-10.8, ¹*J*_{Pt-P} = 2677 Hz) is also present.

Synthesis of [(L¹₂Pt(μ₃-η²-C≡CPh)₂](Pd(C₆F₅)₂)₂], **14B.** cis-[Pd(C₆F₅)₂(thf)₂] (0.100 g, 0.171 mmol) was added to a stirred solution of cis-[Pt(C≡CPh)₂(PPh₂C≡CPh)₂] (**1**; 0.083 g, 0.086 mmol) in CH₂Cl₂ (5 cm³). The resulting solution was immediately evaporated to dryness, and the residue was treated with *n*-hexane (5 cm³) to give a white powder (70% yield). The ³¹P NMR spectrum of this solid shows it to be complex **14B** with a purity >95%. Only traces (less 5%) of complex **6** were also observed. On standing at room temperature (~12 h), considerable decomposition to Pd metal takes place and the only species detected thereafter by ³¹P{¹H} and ¹⁹F spectroscopy were the dinuclear complex **6** and decafluorobiphenyl (C₆F₅-C₆F₅). Identical results were obtained starting from **6** and 1 equiv of cis-[Pd(C₆F₅)₂(thf)₂].

Synthesis of [(Pt(μ-κ(P):η²-PPh₂C≡CPh)₂(μ-η¹:η²-C≡CBu^t)₂](Pt(C₆F₅)₂)₂], **15A.** cis-[Pt(C₆F₅)₂(thf)₂] (0.152 g, 0.229 mmol) was added to a solution of [Pt(C≡CBu^t)₂(PPh₂C≡CPh)₂] (**2**; 0.100 g, 0.107 mmol) in CH₂Cl₂ (10 cm³), and the mixture was stirred for 1 h at room temperature. The resulting yellow solution was evaporated to dryness, and the residue was treated with a mixture of diethyl ether/hexane

(3/2). Cooling at −30 °C for 12 h gives complex **15A** as a pale yellow microcrystalline solid (0.18 g).

¹³C NMR (CDCl₃, −50 °C): ~146, 144, 138.1, 135.3 (br, C₆F₅), 134.5–128.5 (Ph), 124.6 (m, C_β, −C_α≡C_βBu¹), 119.4 (s, Ph), 109.5 (m, C_β, −PC_α≡C_βPh), 87.7 (dd, ²*J*_{C−P_{trans}} = 151.8 Hz, ²*J*_{C−P_{cis}} = 15.5 Hz, C_α, −C_α≡C_βBu¹), 78.3 (d, ¹*J*_{CP} = 77.76 Hz, C_α, P−C_α≡C_βPh), 30.7 (s, −C(CH₃)₃), 31.7, 22.7, 14.4 (s, hexane).

Reaction of *cis*-[Pt(C≡CBu¹)₂L₂] (2**) with *cis*-[Pd(C₆F₅)₂(thf)₂] (Molar Ratio of 1:2).** *cis*-[Pd(C₆F₅)₂(thf)₂] (0.025 g, 0.043 mmol) was added to a solution of *cis*-[Pt(C≡CBu¹)₂(PPh₂C≡CPh)₂] (0.020 g, 0.0215 mmol) in CDCl₃ (0.6 cm³), and a ³¹P NMR spectrum was taken immediately. The initial ³¹P{¹H} NMR spectrum of this mixture at low temperature (−50 °C) revealed the presence of complex **8** (−8.9 ppm) as the main component together with the excess of *cis*-[Pd(C₆F₅)₂(thf)₂]. When the temperature was increased to room temperature, considerable decomposition had taken place (Pd metal) and, in addition to complex **8**, small signals at ~37.6 (d), 33.8 (m), 31.4 (d), and 27.5 (d) ppm were also observed. The ¹⁹F NMR indicated the presence of a considerable amount of C₆F₅−C₆F₅.³¹

Synthesis of [{L₂Pt(μ₃-η²C≡CPh)₂}{Pt(C₆F₅)₂}]₂, **16B.** To a solution of *cis*-[Pt(C≡CPh)₂(PPh₂C≡CBu¹)₂] (**3**; 0.100 g, 0.1075 mmol) in CH₂Cl₂ (10 cm³) was added 0.145 g (0.215 mmol) of *cis*-[Pt(C₆F₅)₂(thf)₂]. After 1 h of stirring, the brown solution was evaporated to dryness and the residue was treated with ¹PrOH (3 cm³) to give a crude solid, which was washed with *n*-hexane. The ³¹P NMR spectra of this solid indicates that complex **16B** is contaminated (~12%) with the dinuclear derivative **9**. Complex **16B** is obtained as a white microcrystalline solid by slow crystallization of the crude material in a CH₂Cl₂/hexane (1:5) mixture at low temperature (−30 °C).

¹³C{¹H} NMR (CDCl₃, −50 °C): 147.4, 144.3, 138.8 (br, C₆F₅), 133.8–126.8 (Ph), 121.37 (m, C_β, P−C_α≡C_βBu¹), 119.7 (s, Ph), 67.5 (d, ¹*J*_{C−P} = 126.7, C_α, P−C_α≡C_βBu¹), 29.3 (s, C(CH₃)₃), 28.5 (s, CMe₃).

Synthesis of [{L₂Pt(μ₃-η²C≡CPh)₂}{Pd(C₆F₅)₂}]₂, **17B.** *cis*-[Pt(C≡CPh)₂(PPh₂C≡CBu¹)₂] (**3**; 0.0608 g, 0.0654 mmol) and 0.0764 g (0.1307 mmol) of *cis*-[Pd(C₆F₅)₂(thf)₂] were mixed in CH₂Cl₂ (5 cm³), and the resulting solution was immediately evaporated to dryness. The residue was extracted with hexane (2 × 5 cm³), giving a beige solid (**17B**:**10** ≈ 90:10 by ³¹P NMR). Recrystallization of this solid (CH₂Cl₂/hexane interface at −30 °C) yielded **17B** as a colorless powder.

When the reaction was monitored by ³¹P{¹H} NMR spectroscopy at 20 °C, we identified a mixture of **17B** and **10** (ratio 80:20). After longer periods, considerable decomposition of **17B** is observed. Thus, in 12 h the intensity of the signal due to **17B** decreases, giving a **17B**/**10** ratio of ~15:85. In addition, the ¹⁹F NMR spectrum reveals the presence of considerable amounts of decafluorobiphenyl.

Synthesis of [{Pt(μ-κ(*P*):η²-PPh₂C≡CBu¹)₂(μ-η¹:η²-C≡CBu¹)₂}{Pt(C₆F₅)₂}]₂, **18A.** Complex **4** (0.072 g, 0.081 mmol) in CH₂Cl₂ (10 cm³) was treated with 0.120 g (0.178 mmol) of *cis*-[Pt(C₆F₅)₂(thf)₂] for 3 h. The resulting solution was evaporated to dryness, and the crude solid (**18A** + **11** (83:17) by ³¹P NMR) was treated with *n*-hexane, giving **18A** as a nearly pure solid (less than 5% of **11** is detected by ³¹P NMR). Yield: 57%. If the initial mixture is stirred for longer periods, complex **18A** decomposes increasing the amount of **11**. Thus, in 7 h, the intensity of the signal due to **11** increases, giving an **18A**/**11** ratio of 55:45.

¹³C NMR (CDCl₃, −50 °C): ~147.6, 144.7, 138.9, 137.9 (br, C₆F₅), 135.6–124.6 (Ph), 113.2 (s, C_β, P−C_α≡C_βBu¹), 108.9 (m, br, this signal can tentatively be assigned to C_β, −C_α≡C_βBu¹), 87.18 (dm, signal poorly resolved, C_α, −C_α≡C_βBu¹), 70.5 (d, ¹*J*_{CP} = 97.1 Hz, C_α, P−C_α≡C_βBu¹), 30.6, 30.4 (s, 2C(CH₃)₃), 29.7, 29.6 (s, br, CMe₃).

Reaction of *cis*-[Pt(C≡CBu¹)₂L₂] (4**) with 2 Equiv of *cis*-[Pd(C₆F₅)₂(thf)₂].** The reaction of **4** (0.0152 g, 0.171 mmol) with *cis*-[Pd(C₆F₅)₂(thf)₂] (0.020 g, 0.034 mmol) in CDCl₃ (0.6 cm³) was monitored by NMR spectroscopy. The dinuclear derivative **12** was observed as the only phosphorous-containing platinum complex (³¹P and ¹H NMR), and no evolution of the ³¹P{¹H} NMR spectrum was observed after 4 or 8 h. The presence of the excess of “*cis*-Pd(C₆F₅)₂” (~117.3 (F_o), −159.9

(F_p), -163.5 (F_m)) together with the signals due to $C_6F_5-C_6F_5$ (-137.6 (m), -149.9 (t), -160.4 (m)) (60:40) are visible in the ^{19}F NMR spectra.

X-ray Crystal Structure Determinations. Suitable crystals of **10**·Me₂CO were grown by slow diffusion of *n*-hexane into a Me₂CO solution of **10**. Suitable crystals of **15A**·0.5C₆H₁₄·0.45C₆H₆ were grown by slow diffusion of *n*-hexane into a dichloromethane/benzene solution of **15A**. Suitable crystals of **16B** were grown by slow diffusion of *n*-hexane into a CH₂-Cl₂ solution of **16B** at -40 °C.

Crystal data and other details of the structure analyses are presented in Table 7. Selected crystals were fixed on top of glass or quartz fibers and mounted on the diffractometers. Unit cell constants were determined from 22 accurately centered reflections with $24^\circ < 2\theta < 26^\circ$ for **10**·Me₂CO, 25 reflections in the range $22.2^\circ < 2\theta < 30.9^\circ$ for **15A**·0.5C₆H₁₄·0.45C₆H₆, and 25 reflections in the range $22.2^\circ < 2\theta < 31.8^\circ$ for **16B**. Data were collected by the $\omega/2\theta$ scans for **10**·Me₂CO and by ω/θ scans for **15A**·0.5C₆H₁₄·0.45C₆H₆ and **16B**. Three check reflections were measured at regular intervals, and no loss of intensity was observed in any case. The position of the heavy atoms were determined from the Patterson map. The remaining atoms were located in successive difference Fourier syntheses. H atoms were added at calculated positions ($C-H = 0.96$ Å) with an isotropic displacement parameter assigned 1.2 times (for the phenyl groups) or 1.5 times (for the methyl groups) that of the corresponding C atom. For **10**·Me₂CO, a molecule of interstitial acetone was found and refined at full occupancy with anisotropic thermal parameters, and no H atoms were added to the acetone molecule. For **15A**·0.5C₆H₁₄·0.45C₆H₆, whereas the positions and thermal parameters of the atoms of the platinum complex were found and refined without difficulty, the electron density corresponding to the solvent molecule atoms was very diffuse. We tried several models and found that the one which gave best results was

the presence of one molecule of *n*-hexane with an occupancy of 0.5, one molecule of benzene with an occupancy of 0.3, and one-half of a molecule of benzene lying around an inversion center whose three carbon atoms had occupancy 0.3. Both solvents had been used in the obtention of the crystals. The interatomic distances and angles were constrained to idealized geometries, and the anisotropic thermal parameters of the carbon atoms of each molecule were constrained to be the same. No attempts to include the solvent hydrogen atoms were made. For **10**·Me₂CO and **16B**, no residual peaks higher than $1\text{ e}/\text{\AA}^3$ remained in the final density map. For **15A**·0.5C₆H₁₄·0.45C₆H₆, the final difference electron density maps showed eight peaks above $1\text{ e}/\text{\AA}^3$ ($1.08-1.02$; largest diff hole -0.76), all of them located in the solvent area. All calculations were carried out using the program SHELXL-93.³²
