Abstract: cyclo(Phe-Pro-D-Ala)2, C34H42N6O6, was synthesized from the hydrochloride of Pro-D-Ala-OMe. NMR data indicate that the two-cis backbone is the major form in solution. Crystals were obtained from a solution of the peptide in a mixture of Me<sub>2</sub>SO and water and have two molecules in the asymmetric unit of a monoclinic cell with a = 18.730 (2) Å, b = 9.239(1) Å, c = 21.544 (2) Å,  $\beta = 95.17$  (2)°, and space group  $P2_1$ . Both molecules have nearly identical conformation and each contain two cis Phe-Pro bonds. There are no intramolecular hydrogen bonds or  $\beta$  turns. The close similarity in the overall backbone conformation of the two independent molecules in the crystal suggests that the conformation in solution is probably the same as that in the crystal. NMR studies confirm this suggestion. The NMR studies included nuclear Overhauser enhancement measurements on solutions in sulfolane, a more viscous solvent chosen to increase the effective rotational correlation time. Evidence indicating a similar solution conformation for the two-cis form of cyclo(Leu-Pro-D-Ala)<sub>2</sub> is given.

Many cyclic hexapeptides of the sequence cyclo(Xxx-Pro-Yyy)<sub>2</sub> have been studied by nuclear magnetic resonance methods.1 They provide convenient models in which to examine sequence and solvent effects on peptide conformation in a limited region of conformation space. 1-3 The subset of these peptides with the sequence cyclo(Xxx-Pro-D-Yyy)2 has been found usually to exist in two forms of average  $C_2$  symmetry, which differ in whether the Xxx-Pro peptide bonds are trans or cis1.2.4 although unsymmetrical forms have recently been found for some examples.<sup>5</sup> The principal factors identified as influencing the position of the two-cis, all-trans equilibrium are the transannular electrostatic or hydrogen bonding interactions among the N-H and C=O units of the Xxx residue and crowding of the Xxx side chain and the δ-CH<sub>2</sub> of Pro, both of which occur in the all-trans form and have been presumed absent or reduced in the two-cis form.<sup>2,4</sup>

Three examples in which all of the peptide bonds are trans have been analyzed by single-crystal X-ray diffractometry, cyclo-(Gly-Pro-D-Phe)<sub>2</sub>, 6 cyclo(Ala-Pro-D-Phe)<sub>2</sub>, 7 and cyclo(Gly-Pro-D-Ala)<sub>2</sub>.8 These all show very much the same conformation, a backbone based on two Type II Pro-D-Yyy  $\beta$  turns that is also definitively identified in solution by NMR studies. Past NMR studies of the form with two cis Xxx-Pro bonds have not yielded sufficient evidence for an unequivocal statement about its conformation, and until now no crystal of a two-cis form has been subjected to X-ray analysis.

We have now obtained crystals of cyclo(Phe-Pro-D-Ala)<sub>2</sub>, hereafter PPA2, in which the two-cis form occurs, and we report here its crystal structure. We also report NMR measurements including nuclear Overhauser enhancements that confirm that the solution conformation, in which transannular interactions between CO-NH units are absent, is like the conformation in the crystal. The crystal of PPA2 used contained water held in channels between hydrophobically packed peptide units in a manner similar to that found for the hydrophobic decapeptide antamanide.9

## **Experimental Section**

 $\it cyclo\, (Phe-Pro-p-Ala)_2$  was prepared starting from the hydrochloride of Pro-p-Ala-OMe.  $^{10}$  This dipeptide was coupled with benzyloxycarbonyl-L-phenylalanine N-hydroxysuccinimide ester in dimethylformamide (DMF) solution. Half of the resulting tripeptide ester was converted to hydrazide by treatment with hydrazine in methanol, and half was hydrogenolyzed in methanol (Pd on carbon) to the N-unblocked tripeptide ester. The two portions were coupled via the azide in DMF to form the protected hexapeptide ester, which was hydrazinolyzed, hy-

drogenolyzed, and finally cyclized in DMF via the azide procedure at about  $4 \times 10^{-3}$  M. The procedures have been described in detail elsewhere for other peptides.<sup>4</sup> Intermediates were isolated free of peptide or peptide-like impurities according to thin-layer chromatography, but they were not crystallized for analysis. The cyclic hexapeptide was readily isolated from the cyclization reaction mixture by evaporation of the solvent and sonication of the residue with water until it crystallized. It was twice recrystallized from 2-propanol and obtained in 25% yield from the dipeptide starting material. The yield of the cyclization step itself was 51%. An analytical sample was dried at 100 °C under vacuum overnight and decomposed above 300 °C without melting.

Anal. Calcd for  $C_{34}H_{42}N_6O_6$ : C, 64.74; H, 6.71; N, 13.33; Found: C, 64.49; H, 6.67; N, 13.20.

X-ray Crystallography. Well-formed crystals were grown from a solution of PPA2 in Me<sub>2</sub>SO and water. The crystals were stable outside the mother liquor. A crystal of dimensions  $1.6 \times 0.8 \times 0.3$  mm mounted on a glass fiber was used for data collection. Unit cell dimensions and intensity data were obtained with an Enraf-Nonius CAD4 atomatic diffractometer. The cell parameters were measured by the least-squares fit using 25 reflections. PPA2 crystallizes in a monoclinic unit cell of dimensions a=18.730 (1) Å, b=9.239 (1) Å, c=21.544 (2) Å, and  $\beta=95.11$  (2)°. There are four molecules in the unit cell of space group  $P2_1$  with a volume of 3713 A<sup>3</sup>.

Intensity data up to  $2\theta = 154^{\circ}$  were measured by using Cu  $K_{\alpha}$  ( $\lambda$ 1.5418 Å) by the  $\omega$ -2 $\theta$  scan technique. During the course of data collection three reflections monitored every 2 h indicated no crystal deterioration. A total of 8857 unique reflections were measured of which 7765 were above  $3\sigma(I)$ , and these were used in structure determination and refinement. The intensity data were corrected for Lorentz-polarization effects and absorption.

The structure was solved by using the direct methods program MUL-TAN 80.11 After repeated trials 160 phase sets generated by using 488

<sup>(10)</sup> Nicolaides et al. (Nicolaides, E.; Dewald, H.; Westland, R.; Lipnik, M.; Posler, J. J. Med. Chem. 1968, 11, 74-79) report the preparation of Z-Pro-D-Ala-OMe, the precursor of the amino component, but no analysis. Our preparation had mp 90–92 °C. Anal. Calcd for  $C_{17}H_{22}N_2O_5$ : C, 61.06; H, 6.63; N, 8.38. Found: C, 61.01; H, 6.64; N, 8.33.

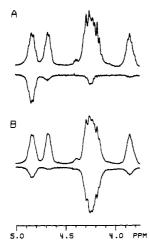

Figure 1. Nuclear Overhauser enhancements in cyclo(Phe-Pro-D-Ala)<sub>2</sub> in sulfolane, 30 °C. Difference spectra are the lower curves. (A) Irradiation into  $H^{\alpha}_{Phe}(cis)$  at 4.84 ppm, showing NOE of  $H^{\alpha}_{Pro}(cis)$  and transfer of saturation to  $H^{\alpha}_{Phe}(trans)$ . (B) Irradiation of  $H^{\alpha}_{Pro}(cis)$  at 4.28 ppm and into overlapping  $H^{\alpha}_{Pro}(trans)$  and  $H^{\alpha}_{Ala}(trans)$  showing NOE of  $H^{\alpha}_{Phe}(cis)$ . Effect on  $H^{\alpha}_{Ala}(cis)$  may be saturation transfer from  $H^{\alpha}_{Ala}(trans)$ ; no NOE is anticipated.

reflections with E > 1.75 and three hand-picked origin-defining reflections gave an E map that revealed the positions of 88 or 92 non-hydrogen atoms of the two peptide molecules. The remaining 4 atoms of the peptide molecules and 8 water molecules were obtained from successive weighted Fourier maps.

A structure factor calculation with 100 atoms having an isotropic temperature factor of 4.7  $\text{\AA}^2$  gave an initial R factor of 26.9%. A few cycles of block-diagonal least-squares refinement dropped the R factor to 13.3%. At this stage all 100 atoms were treated anisotropically and a few cycles of refinement brought the residual down to 0.077. Hydrogen positions were calculated and were included in the refinement. The final R factor for all 7765 reflections was 0.059.

NMR Measurements. NMR data from dimethyl sulfoxide and tetramethylene sulfone solutions were obtained by using a Nicolet NT spectrometer system operating at 300 MHz for protons. Sixteen K words of data were employed for a 4-kHz sweep width. Proton resonance assignments were made in the usual manner by decoupling and solvent variation (dimethyl sulfoxide-tetramethylene sulfone) experiments. Carbon resonance assignments were made on the basis of chemical shifts. Concentrations were about 10 mM for protons and 50 mM for carbon measurements. Two cis/all-trans ratios were determined from areas of the Ala methyl resonances in fully relaxed spectra. The dominant form was identified from carbon spectra.

Interproton nuclear Overhauser enhancements (NOE) were measured by using a 2-s presaturation period followed by a 90° observe pulse and acquisition with the decoupler power off.  $T_1$  of all of the proton resonances in both two-cis and all-trans forms had been determined to be less than 0.4 s in dimethyl sulfoxide. Transformed spectra were subtracted from spectra in which  $H_2$  was set in an interval between resonances. Minimal decoupler power was used to avoid saturation of the adjacent resonances. Areas of the difference spectra were used to estimate the enhancements; all enhancements observed were negative. An example of the NOE measurements is given in Figure 1.

Materials. Tetramethylene- $d_8$  sulfone, 98% isotopic enrichment, was obtained from Merck (Isotopes) and dimethyl- $d_6$  sulfoxide (99.96%) from Aldrich.

## **Results and Discussion**

X-ray Crystallography. The final atomic parameters are listed in Table I. Figure 2 shows the numbering scheme used. Tables IIa and IIb give the bond lengths and angles in the two independent peptide molecules. The average standard deviations in bond lengths and angles are 0.003 Å and 0.3°, respectively. The agreement among comparable bond lengths and angles in the two crystallographically independent molecules is satisfactory, and

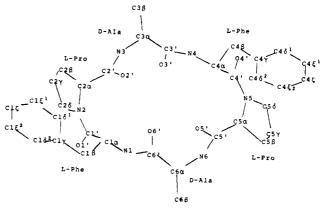

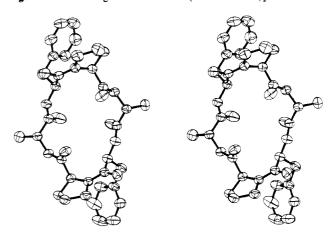

Figure 2. Numbering scheme used for (Phe-Pro-D-Ala)<sub>2</sub>.

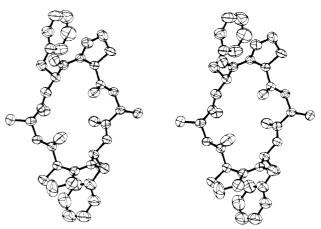

Figure 3. Stereodrawing showing the conformation of the two molecules of PPA2.

the bond lengths and angles are fairly similar to those reported in the literature.  $^{15}$ 

The conformations of the two peptide molecules are shown in Figure 3 (ORTEP<sup>13</sup> drawing), and observed torsional angles are listed in Table III. Both molecules have near twofold symmetry. All L-Phe-L-Pro peptide bonds are cis, and they show considerable deviations from planarity, with  $\omega$  values varying between -3° and -21°. Comparable nonplanarity in cis peptide bonds has already been noted in the structure of the Mg<sup>2+</sup> complex of cyclo(Gly-L-Pro-L-Pro)<sub>2</sub>. In the present two-cis structures there are none of the internal hydrogen bonds or  $\beta$  turns that have been observed

in crystal structures of other  $cyclo(Xxx-Pro-Yyy)_2$  peptides, where all of the peptide bonds have been trans.<sup>6-8</sup>

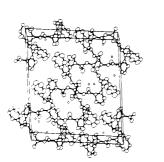

The backbone torsional angles show some significant differences for corresponding residues within and between the hexapeptide molecules. The nonplanarity of the cis peptide bonds in molecule A is less (-3° and -12°) than that in molecule B (-16° and -21°). The prolines show variations as well. In molecule A both proline rings are  $C^{\gamma}$ -endo, while in B one is endo and the other exo. In spite of the individual variation in torsional angles, the overall backbone conformations of the two molecules are quite similar, which suggests that the general conformation adopted by the peptide ring in the crystal is a stable one, not strongly determined by the environment.

Figure 4 shows the crystal packing. There are four peptide molecules and 16 water molecules in the unit cell. The hydrophobic residues (shaded) tend to segregate to form hydrophobic and hydrophilic channels in the crystal. The hydrophilic channels are occupied by the water molecules. The hydrogen bond distances are tabulated in Table IV and the hydrogen bonding scheme is shown in Figure 5. The water molecules are all hydrogen bonded to at least one peptide carbonyl oxygen. Nine of the 12 carbonyl oxygens are hydrogen bonded to water molecules. The carbonyl oxygens of the D-alanine residues of molecule A are bridged by one water molecule (OW1), and in B a water molecule (OW7) bridges the D-alanine carbonyls. In addition to the water hydrogen bonding there is also hydrogen bonding between one alanine N-H

of molecule B (N3) and one alanine C-O of molecule A (O1'). The carbonyl oxygen O2' (of molecule B) is not involved in any hydrogen bonding. In the crystal the two peptide molecules have different hydrogen bonding schemes and this coupled with the packing forces might be resposible for the observed differences in the values of the conformational angles.

NMR Studies of the Conformation of cyclo (Phe-Pro-D-Ala)<sub>2</sub> in Solution. The spectra of the two-cis and the all-trans backbones of cyclo(Phe-Pro-D-Ala)<sub>2</sub> in solution are distinct. We are concerned here with the two cis form.

Coupling constant and chemical shift data of cyclo(Phe-Pro-D-Ala)<sub>2</sub> do not sufficiently limit the possible backbone conformations for the two-cis form, so that additional information was

be a consequence of the rotational correlation time of the peptide rather than an indication of internuclear distances, sulfolane (tetramethylene sulfone), a solvent similar to Me<sub>2</sub>SO but more viscous, was used for additional studies. Sulfolane has about 5 times the viscosity of Me<sub>2</sub>SO, 9.03 vs. 1.65 cP at 35 °C.<sup>16</sup> Solutions of the peptide in sulfolane and in 70% sulfolane/30% Me<sub>2</sub>SO do indeed show definitive (negative) enhancements.

Table V gives conformationally significant chemical shift and coupling constant data for the two-cis form in Me<sub>2</sub>SO and sulfolane solutions. Table VI shows the backbone proton-proton Overhauser enhancements observed in sulfolane and in 70% sulfolane/30% Me<sub>2</sub>SO solutions.

The two-cis form of cyclo(Phe-Pro-D-Ala)<sub>2</sub> shows the same H<sup>N</sup> proton resonance temperature dependences and coupling constants, the same  $H^{\alpha}$  chemical shifts, and the same abnormally high field Ala  $\beta$ -methyl resonance (0.82 ppm) in sulfolane as in Me<sub>2</sub>SO. The peptide is not sufficiently soluble in sulfolane for <sup>13</sup>C measurements, but these could be made on 70% sulfolane/30% Me<sub>2</sub>SO solutions. The conformationally significant Pro  $C^{\beta}$  and  $C^{\gamma}$ chemical shifts in the mixed solvent are found to be close to those found for Me<sub>2</sub>SO solution. These similarities indicate similar conformations for the Phe peptide in Me<sub>2</sub>SO and sulfolane. Nuclear Overhauser enhancement data obtained from sulfolane solutions can therefore be adduced as evidence of the conformation in Me<sub>2</sub>SO as well as in sulfolane.

The two-cis/all-trans ratio for cyclo(Phe-Pro-D-Ala), is 9 in Me<sub>2</sub>SO, 3 in 70% sulfolane/30% Me<sub>2</sub>SO, and 1.1 in pure sulfolane. This observation is consistent with earlier findings that decreasing solvent basicity is one factor favoring the internally hydrogen bonded all-trans form of cyclo(Xxx-Pro-D-Yyy)<sub>2</sub> peptides.<sup>2,4</sup> Although sulfolane has about the same dielectric constant as Me<sub>2</sub>SO (43.3 vs. 46.7 at 25 °C<sup>16</sup>), it is a considerably poorer hydrogen bond acceptor, as indicated by the heats of complex formation with p-fluorophenol in the pure solvents (-4.25 and -7.21 kcal/mol, respectively). A related conformationally significant observation is that the H<sub>Phe</sub> resonance of the two-cis form moves 1.4-ppm upfield on going from Me<sub>2</sub>SO to sulfolane. Since the conformation is similar in the two solvents, this reflects transfer of a solvent-exposed proton to a poorer hydrogen bond accepting solvent. 18,19

The observed H-N- $C^{\alpha}$ -H coupling constants are consistent with a backbone dihedral angle  $\phi_{\rm Phe}$  of -120  $\pm$  15°. For  $\phi_{\rm D-Ala}$ , values of  $-60 \pm 15^{\circ}$ , near 75°, or near 165° are all consistent with the experimental result.<sup>20,21</sup> The -60° region, which puts H<sup>N</sup> and  $H^{\alpha}$  of Ala s-cis, is not consistent with the small Overhauser effect on the  $H_{Ala}^{\alpha}$  lines upon irradiation into the  $H_{Ala}^{N}$  resonances. (See footnote b to Table VI and the discussion below of the NOE

The value of about 11 ppm for the chemical shift difference between the Pro  $\beta$ - and  $\gamma$ -carbon resonances is consistent with a cis Phe-Pro peptide bond and correlates with  $\psi_{\text{Pro}}$  near 165° or -45°. 22 A high positive value, which puts  $H_{Pro}^{\alpha}$  and  $H_{Ala}^{N}$  nearly cis, is supported by the -20% enhancement of the  $H_{Pro}^{\alpha}$  resonance when  $H_{Ala}^H$  is irradiated. Larger Overhauser effects (-30%) are observed between  $H_{Ala}^{\alpha}$  and  $H_{Phe}^{N}$  suggesting that  $\psi_{Ala}$  is near -120°. Finally, -30% Overhauser effects are also observed between  $H_{Pro}^{\alpha}$  and  $H_{Phe}^{\beta}$ . These two protons are close when the

<sup>&</sup>lt;sup>a</sup>S = sulfolane, tetramethylene sulfone; D = dimethyl sulfoxide;  $(r^{-6}/\sum r^{-6})_{av}$  is the fraction of a maximum NOE to be expected for the conformation found in the crystal. See text. Protons within 3 Å of the observed proton are included in the sum. <sup>b</sup> For  $\psi_{\text{D-Ala}} = -60^{\circ}$ ,  $r^{-6}/\sum r^{-6}$  is calculated to be 0.26 if  $\phi_{\text{D-Ala}} = -120^{\circ}$  and 0.47 if  $\phi_{\text{D-Ala}} = +60^{\circ}$ .

Phe-Pro peptide bond is cis and closest when  $\psi_{\text{Phe}}$  is near 120°

Comparing the average of the four sets of backbone dihedral angles for each kind of residue in the crystal of cyclo(Phe-Pro-D-Ala)<sub>2</sub> with the values estimated from the solution NMR data, we have the data in Table VII.

Table V also presents for comparison Me<sub>2</sub>SO data for cyclo-(Leu-Pro-D-Ala)<sub>2</sub>, which is about 50% two-cis in dimethyl sulfoxide. The HN chemical shifts and their relative temperature sensitivities, the H-N-C $^{\alpha}$ -H coupling constants, the  $\hat{H}^{\alpha}_{Pro}$  and  $H^{\alpha}_{Ala}$  chemical shifts, and the  $C^{\beta}_{Pro}$  and  $C^{\gamma}_{Pro}$  chemical shifts, all conformationally sensitive observables, are quite similar for the two-cis forms of the Phe and Leu peptides in dimethyl sulfoxide. This suggests that the backbone conformation of the two-cis form of cyclo(Leu-Pro-D-Ala)<sub>2</sub> is similar to that of cyclo(Phe-Pro-D-Ala)2.

Returning the NOE data for cyclo(Phe-Pro-D-Ala), an approximate test of agreement between the steady state nuclear Overhauser effects and the interproton distances in the crystal can be made under some restrictive assumptions. The least valid

of these is the assumption of a rigid structure with a single correlation time for reorientation of the interproton vectors. Other assumptions are relaxation only by proton-proton dipolar interaction, which restricts the test to carbon bound protons, and negligible spin polarization effects. The effect on the resonance of proton i or irradiating proton s should then be proportional to  $r_{\rm is}^{-6}/[r_{\rm is}^{-6} + r_{\rm is}^{-6}]$  where n refers to the other protons contributing to the relaxation of proton i.<sup>23</sup> The averages of the values of this term for the four sets of internuclear distances in the crystal appear in Table VI. Protons within 3 Å of proton i were included. The proportionality between these distance ratios and the observed Overhauser effect is the maximum proton-proton NOE for a given correlation time and Larmor frequency. From the facts that zero NOE's were observed in Me<sub>2</sub>SO solutions of cyclo(Phe-Pro-D-Ala), and that the viscosity of sulfolane is about five times that of Me<sub>2</sub>SO, an approximate effective correlation time  $(3 \times 10^{-9})$ s) and maximum NOE (-0.85)<sup>23</sup> can be estimated by assuming a linear dependence of effective correlation time on viscosity and by using eq 11 of ref 23. The calculated and found values for the larger effects are in sufficient agreement, considering the sensitivity of  $r_{is}^{-6}$  to  $r_{is}$  at the 2.1-2.3-Å distances of these four interactions found in the crystal.

Coupling constant and NOE data thus indicate that the average peptide backbone of the two-cis form of cyclo(Phe-Pro-D-Ala)<sub>2</sub> in solution is similar to the conformation found in the crystal.

It is of interest to consider the temperature sensitivities of the H<sup>N</sup> resonances in the light of this probable solution conformation. Neither the Phe nor Ala peptide protons are at all sequestered from the solvent by the peptide backbone, according to space-filling models, and they are not involved in intramolecular hydrogen bonds. Nonetheless  $d\delta/dT$  in dimethyl sulfoxide is 0.0053

ppm/deg for  $H_{\rm Phe}^{\rm N}$ , a value considered to indicate solvent exposure, but only 0.0002 ppm/deg for  $H_{\rm Ala}^{\rm N}$ , a value usually taken to indicate shielding from the solvent. This distinction occurs in other peptides of the  $cyclo(Xxx-Pro-D-Ala)_2$  series. The observed temperature coefficients (Xxx/D-Ala) for analogous peptides in which Phe is replaced by the indicated Xxx residue are as follows: Xxx = Ala, 0.003/0.006, Leu, 0.004/0.0027; Val, 0.005/0.0013 and Glu(O-t-Bu), 0.0046/0.0024. The distinction is absent, however, in methanol: Phe, 0.003/0.0029, and Leu, 0.0055/0.0065.<sup>24</sup> The temperature coefficients in dimethyl sulfoxide and the much larger upfield shift of the  $H_{\rm Phe}^{\rm N}$  resonance on shifting from dimethyl sulfoxide to sulfolane do suggest that  $H_{\rm Phe}^{\rm N}$  is more exposed to dimethyl sulfoxide than is  $H_{\rm Ala}^{\rm N}$ . A visible difference between them is that the Ala N–H group is flanked by  $H_{\rm Pro}^{\alpha}$  and the Ala  $\beta$ -CH<sub>3</sub> group,

while the Phe N-H group is flanked by  $H_{Ala}^{\alpha}$  and the Phe carbonyl oxygen

(24) Zhu, P.-P.; Go, A.; Kopple, K. D., unpublished

Whether and how this difference explains the apparent solvent exposure is yet open to discussion.

One difference between crystal and solution conformations is apparent. Analysis of the  $H_{Phe}^{\alpha}-H_{Phe}^{\beta}$  coupling constants<sup>25</sup> shows that one  $\alpha-\beta$  rotamer with a trans pair of protons is dominant, about 0.65 mol fraction. The 0.3-ppm upfield shift of the Ala methyl protons from their normal value near 1.1 ppm (as in  $cyclo(\text{Leu-Pro-D-Ala})_2$ , see Table V) suggests that the favored rotamer has  $\chi_1 = -60^{\circ}$ . In the crystal  $\chi_1 = 180^{\circ}$ ; were this true in solution, large upfield shifts of some Pro protons would be expected. These were not found.

## Ferricyanide Oxidation of Dihydropyridines and Analogues

Michael F. Powell, James C. Wu, and Thomas C. Bruice\*

Contribution from the Department of Chemistry, University of California at Santa Barbara, Santa Barbara, California 93106. Received December 12, 1983

Abstract: The reaction of the N<sup>1</sup>-substituted dihydronicotinamides (1-6), N-benzyl-3-carbomyl-1,4-dihydropyridine (7), and tritiated N-methylacridan (8) with  $Fe(CN)_6^{3-}$  is first order in  $[Fe(CN)_6^{3-}]$  and [substrate]. The oxidations of 1-7 were followed spectrophotometrically (350 nm) while the oxidation of 8 was followed by radiometric assay. In the instances of 1, 2, and 8 kinetic deuterium isotope effects were determined by employing dideuterio analogues (of 1 and 2) and deuterio-tritium substitution (for 8). Under the conditions of  $[Fe(CN)_6^{2-}] >> [PyL_2] < [Fe(CN)_6^{4-}]$ , it is found that the reciprocal of the pseudo-first-order rate constant increases with increase in  $[Fe(CN)_6^{4-}]$ —at constant  $[Fe(CN)_6^{3-}]$ . This inhibition of the  $Fe(CN)_6^{3-}$  oxidation of  $PyL_2$  (L = H or D) compounds by  $Fe(CN)_6^{4-}$  decreases with increase in the electronegativity of the pyridine nitrogens. This observation finds explanation in the 1e<sup>-</sup> oxidation of PyH<sub>2</sub> to PyH<sub>2</sub><sup>+</sup> by Fe(CN)<sub>6</sub><sup>3-</sup> and reduction of PyH<sup>+</sup> to PyH<sub>2</sub> by  $Fe(CN)_6^{4-}$ . A plot of the log of the rate constants  $(k_1)$  for the  $1e^-$  oxidations of a series of  $N^1$ -substituted dihydropyridines vs. the log of the rate constants  $(k_{HH})$  for hydride transfer from N<sup>1</sup>-substituted dihydropyridines to N-methylacridinium ion is linear (PyH<sub>2</sub> = 1, 2, 4, 6, 7) with slope  $\sim 1$ . This finding shows that equal positive charges are generated on the pyridine nitrogen in the transition states for both the 1e oxidation of and H abstraction from any of the dihydropyridines. This result establishes that such linear free energy plots do not differentiate between the mechanism of formation of PyH<sub>2</sub>+ and PyH+ by  $1e^-$  and  $H^-$  oxidations. The point in the  $\log k_1$  vs.  $\log k_{\rm HH}$  plot for 8 exhibits a deviation of >10<sup>3</sup> commensurate with the greater stability of acridinyl radical cation as compared to radical cations generated from N<sup>1</sup>-substituted dihydropyridines. The observation that the ferricyanide oxidation is first order in Fe(CN)<sub>6</sub><sup>3-</sup> and that both primary deuterium kinetic isotope effects (e.g., PyH<sub>2</sub> vs. PyD<sub>2</sub>) and Fe(CN)<sub>6</sub><sup>4-</sup> inhibition are observed establishes that PyH<sub>2</sub><sup>+</sup>· must exist as an intermediate. Either 1e<sup>-</sup> transfer from PyH<sub>2</sub> to Fe(CN)<sub>6</sub><sup>3-</sup> or H<sup>+</sup> transfer from PyH<sub>2</sub><sup>+</sup>· to yield PyH· may be rate determining. The mechanism of Scheme I is favored in that it allows a rationalization of these observations. On increase in electron withdrawal, partitioning of PyH<sub>2</sub><sup>+</sup>· species to PyH· by H<sup>+</sup> loss becomes favored over partitioning of PyH<sub>2</sub><sup>+</sup>· to PyH<sub>2</sub> by reduction with Fe(CN)<sub>6</sub><sup>4-</sup>. This is shown not only by the kinetically determined partition coefficient but also by the lack of inhibition of Fe(CN)63- oxidation of the electron deficient 6 by Fe(CN)<sub>6</sub><sup>4</sup>. Stabilization of the radical cation, as seen with 8, is accompanied by marked Fe(CN)<sub>6</sub><sup>4</sup> inhibition and a large kinetic deuterium isotope effect accompanying  $H^+$  transfer from the radical cation. The inhibiting effect of  $O_2$  is attributed (Scheme II) to the  $1e^-$  oxidation of PyH· to PyH<sup>+</sup> (not rate determining) by  $O_2$  and reaction of the resultant  $O_2^-$  with  $PyH_2^+$  to regenerate  $O_2$  and  $PyH_2$ .

Much of the controversy<sup>1</sup> regarding the detailed mechanism of NADH model compound (PyH,H) reduction of organic com-

pounds that do not possess appreciable 1e<sup>-</sup> redox potentials has largely been resolved with the conclusion that H<sup>-</sup> transfer is
