1918 Notes Inorganic Chemistry

individual measurements do not follow a temperaturedependent trend and, therefore, should be considered as experimental errors and not significant in terms of a change in a configurational equilibrium.

In conclusion, the constant value of the dipole moments measured in solution over the given temperature range in addition to published4 infrared and Raman spectra and high-temperature nmr studies seem to provide strong evidence for a cis-cis (II) configurational equilibrium in solution.

## Chlorine Pentafluoride. **Preparation and Properties**

By D. PILIPOVICH, W. MAYA, E. A. LAWTON, H. F. BAUER, D. F. SHEEHAN, N. N. OGIMACHI, R. D. WILSON, F. C. Gunderloy, Jr., and V. E. Bedwell

Received April 10, 1967

Three communications reporting the synthesis of  $ClF_5$  have appeared. <sup>1-3</sup> This halogen fluoride has been under independent investigation in the Rocketdyne laboratories, and we wish now to report on some of our work in this area. Chlorine pentafluoride was first prepared in low yields in our laboratories by reactions of F2 with chlorine and chlorine-containing compounds in a glow discharge at  $-196^{\circ}$ . Despite the very small quantities of ClF5 isolated, we established the fact that Cl<sub>2</sub> and F<sub>2</sub> were sufficient for its formation and inferred its structure from the infrared spectrum subsequently published by Begun, et al.4 Molecular weights determined from vapor density measurements of impure CIF, also inferred the composition.

What we believe to be the most useful laboratory preparation of CIF<sub>5</sub> involves the fluorination of an alkali metal chlorotetrafluoride, MClF4. Those examined include KCIF<sub>4</sub>, RbClF<sub>4</sub>, and CsClF<sub>4</sub>. Although all salts yielded CIF<sub>5</sub> upon fluorination, the cesium and potassium salts were investigated more extensively in this study. The general reaction for the salt fluorination is

$$MClF_4 + F_2 \longrightarrow MF + ClF_5$$
 (1)

From the above equation it is seen that only one condensable gaseous product should be obtained. This was confirmed repeatedly by experiment; i.e., pure CIF<sub>5</sub> was obtained in these reactions.

The conversions of MClF<sub>4</sub> to ClF<sub>5</sub> were variable.

Using KCIF<sub>4</sub>, conversions from 1 to 25% have been observed. The lowest conversion was observed at 80°. while at 150° a consistent conversion of 10% was noted. Higher conversions were obtained with CsClF4 and ranged from 25 to 90%. With both salts, however, pure ClF<sub>5</sub> was the only condensable gaseous product.

Chlorine pentafluoride is a typical interhalogen fluoride in that it is a corrosive, highly oxidizing substance. It is colorless in the gas phase, water white in the liquid phase, and freezes to a white solid. Vapor pressures were measured on the range -79.0 to  $+25^{\circ}$ and are fitted to the equation  $log P_{mm} = 7.2683 1137.16/T(^{\circ}K)$ . Measured vapor pressures at the noted temperatures are [T (°C), P (mm)]: -79.2,16.5; -63.2, 55.0; -50.0, 128.0; -45.3, 166.0; -35. 290.0; -26.2, 453.5; -23.7, 507; -17.9, 634.5;-14.5, 734.5; -0.2, 1293; +24.8, 2855. The normal boiling point is  $-14.0^{\circ}$  and the melting point is  $-103 \pm 4^{\circ}$ . The derived Trouton constant of 21.8 shows CIF<sub>5</sub> to be a nonassociated liquid. The density of CIF5 was measured in the range of -80 to  $-23^{\circ}$ . The density-temperature relationship of d (g/ ml) =  $2.696 - (3.08 \times 10^{-3} T(^{\circ}K))$  is derived from the measured values (°C, g/ml): -80, 2.100; -57, 2.0361; -23, 1.922.

The thermal stability of ClF<sub>5</sub> is somewhat less than that of ClF<sub>3</sub>. The equilibrium

$$CIF_5 \rightleftharpoons CIF_3 + F_2$$

was found to be established fairly readily above 165° and has been studied in detail.5

Chlorine pentafluoride was smoothly reduced by burning with ammonia to give a mixture of NH<sub>4</sub>Cl and NH<sub>4</sub>F. Multiple analyses of the combustion products gave an F/Cl ratio of 4.92. These agreed closely with chromatographic assays, using the technique of Lysyj and Newton,6 which showed the presence of small quantities of Cl2. The molecular weight was determined from the vapor density and was found to be 128 (calcd, 130.5).

The high-resolution F19 nmr spectrum for CIF5 has been recorded using a Varian DP-60 spectrometer operating at 56.4 Mc. The spectrum was obtained on a 50 mole % solution of CIF<sub>5</sub> in CFCl<sub>3</sub>. Two band structures were noted in the nmr spectrum. A strong doublet was recorded at -247 ppm (relative to CFCl<sub>3</sub>) and a weak quintet at -412 ppm. The coupling constant for the band structures is J = 130 cps. The seven-component F19 spectrum recorded confirms the C<sub>4v</sub> symmetry deduced from infrared and Raman studies.3

A stable mass-cracking pattern for CIF5 has been obtained with a CEC 21-103 C mass spectrometer. Observed ions, excluding Cl37 isotopes, with the relative abundance were [m/e, ion, abundance (%)]: 111,  $C1F_4^+$ , 82.0; 92,  $C1F_3^+$ , 18.6; 73,  $C1F_2^+$ , 100.0; 54, CIF+, 21.0; 46, CIF<sub>3</sub><sup>2+</sup>, 3.5; 37.5, CIF<sub>2</sub><sup>2+</sup>, 0.5; 35, Cl+,

11.4. The base peak corresponding to the ion  $ClF_2^+$  was most unexpected inasmuch as under the same conditions in our instrument no m/e 73 was observed from  $ClF_3$  except those for chlorine.<sup>7</sup>

Chlorine pentafluoride appears to be less corrosive to metals than CIF<sub>3</sub>. A large sample has been stored in a Hoke 304 stainless steel cylinder for over 4 years without detectable decomposition. Contrary to the initial report on CIF<sub>5</sub><sup>1</sup> we have found CIF<sub>5</sub> to be extremely reactive toward water and water vapor. The hydrolysis of CIF<sub>5</sub> was carefully studied in Kel-F and the experimentally established stoichiometry is indicated as

$$C1F_5 + 2H_2O \longrightarrow FC1O_2 + 4HF$$

Subsequent decomposition of FClO<sub>2</sub> (in metal systems) no doubt accounts for the presence of Cl<sub>2</sub>, ClO<sub>2</sub>, and FClO<sub>3</sub> frequently encountered in contaminated ClF<sub>5</sub>. These same products are encountered whenever ClF<sub>5</sub> comes into contact with a hydroxylic function in any form.

When CIF<sub>5</sub> was handled in Kel-F or Teflon apparatus above its boiling point, it was found to be appreciably and rapidly soluble in the polymer. After the CIF<sub>5</sub> had been in contact with the polymer at room temperature for 1 day, it was found that neither evacuation under high vacuum nor washing with water removed all of the CIF<sub>5</sub> from the polymer; only after pumping for days in a vacuum system were the last traces of CIF<sub>5</sub> removed.

As predicted, CIF<sub>5</sub> is a vigorous fluorinating agent. With the possible exception of carbon, the first-row nonmetals did not react with CIF5 at 150° in 16 hr. In contrast, second- and third-row nonmetals except chlorine were reactive even at ambient temperature. Carbon reactivity varied with its form. Activated charcoal reacted vigorously at ambient temperature to form Cl<sub>2</sub>, CF<sub>4</sub>, CF<sub>3</sub>Cl, and C<sub>2</sub>F<sub>6</sub>. Lampblack with 1% volatile impurities reacted only partially at 150°. Graphite powder and pressed graphite rod took up CIF5 corresponding to 10 wt % of the graphite but only CIF5 was found in the volatiles recovered. Basic hydrolysis of such graphitic material was accompanied by a deflagration and yielded products similar to those of CIF<sub>5</sub> hydrolyses. The graphite rod crumbled on prolonged exposure to CIF5. The above results suggest an intercalation compound between graphite and CIF5.

Among the products of reaction between  $ClF_5$  and basic, neutral, and acidic hydroxides were HF, O<sub>2</sub>, chlorine, and chlorine dioxide.  $ClF_5$  attacked CO, PO, and SO multiple bonds but not NO or ClO multiple bonds. Of particular interest was the scant amount of toxic, noxious, or otherwise hazardous gas products in the reactions of  $ClF_5$  with  $Na_2B_4O_7 \cdot Na_2S_2O_3 \cdot 9H_2O$  and  $NaHCO_3$ . Metal fluoride hydrates reacted with  $ClF_5$  at ambient temperature with the exception of  $MgF_2 \cdot xH_2O$  which had to be warmed for complete reaction.

## Experimental Details

Materials.—Chlorine trifluoride was obtained from the Matheson Co. The reactors used for the pressure fluorinations were either Monel or 304 stainless steel and equipped with Hoke M343 valves. The discharge apparatus used for the synthesis of CIF<sub>5</sub> was similar to that described elsewhere.<sup>8</sup>

Preparation by Electrical Discharge.—A 60-1. stainless steel tank was filled to 1 atm with a mixture of 10 parts of fluorine and 1 part of chlorine (by volume). The gas was pumped through an electrical discharge cell cooled in a solid  $CO_2$  and trichloroethylene mixture, a U trap at  $-196^{\circ}$ , and a manostat of the bubbler type filled with Fluorolube oil that maintained a pressure in the train of 30 mm; the pump was protected by a fluorine absorber made of NaCl and soda lime and a liquid nitrogen trap. The contents of the  $-196^{\circ}$  trap adjacent to the discharge apparatus was fractionated in a metal vacuum line through traps cooled to -112, -126, and  $-196^{\circ}$ . The middle trap contained  $CIF_5$ , and the other traps contained  $CIF_3$  and  $CIF_7$ , respectively. The yield was of the order of 1 cc of  $CIF_5/4000$  cc of gas mixture used.

Synthesis of ClF<sub>5</sub> from Alkali Metal Chlorotetrafluorides.—A previously passivated 500-ml stainless steel Hoke cylinder was loaded with 76.0 g (0.5 mole) of anhydrous cesium fluoride in a drybox, and 50 g (0.55 mole) of ClF<sub>3</sub> was condensed therein from a metal vacuum line. The reactor was heated for 4 hr at 80°. Most of the ClF<sub>3</sub> was found to have reacted after this treatment. Fifteen liters (0.67 mole) of fluorine was then condensed into the reactor which was then heated for 22 hr at 150°. After removal of the excess fluorine, 26 g (0.2 mole) of pure ClF<sub>5</sub>, representing a 40% conversion, was distilled out of the reactor. Essentially the same procedure was employed with RbF and KF; the conversions with KF were not as high and ranged between 10 and 25%.

Acknowledgment.—Support for this work was generated through Contracts Nonr 1818(00), Nonr 3451(00)-ARPA Order No. 26.61, and AFO4(611)-7023. We also thank Dr. V. Dayan for the chromatographic analyses and Dr. C. Greenough for the nmr spectrum.

## Complexes of Sulfur Dioxide with Ionic Azides

By R. J. SHOZDA

Received April 10, 1967

Numerous reactions between sulfur dioxide and inorganic salts have been reported. For example, potassium cyanide,<sup>1</sup> potassium iodide,<sup>2</sup> and alkali metal fluorides<sup>3</sup> are known to combine with sulfur dioxide, and in many cases the products undergo irreversible reactions. However, the reaction of an azide salt with sulfur dioxide has not been described.

During the course of a study of azides, it was observed that the alkali metal azides reversibly absorb sulfur dioxide at room temperature. The apparent ease of
