## Specific Phosphorylation of the 2'- and 3'- Positions in Ribonucleosides

By A. W. SCHWARTZ

(Department of Exobiology, University of Nijmegen, Nijmegen, Netherlands)

Summary Adenosine is phosphorylated in alkaline solution by sodium trimetaphosphate to yield exclusively the 2'-and 3'-monophosphates.

The reagent sodium trimetaphosphate has been reported to phosphorylate alcohols and carbohydrates in alkaline solutions.¹ During the course of an investigation into the phosphorylation of nucleosides by a variety of condensed phosphates in aqueous solution,² sodium trimetaphosphate was found to react specifically with the 2′- and 3′- hydroxygroups of a ribonucleoside.

Sodium trimetaphosphate was synthesized by annealing a long-chain sodium polyphosphate preparation (Graham's salt) at  $520^{\circ}$  for 12 hr. The product was chromatographically homogeneous,<sup>3</sup> and was resistant to the action of  $E.\ coli$  alkaline phosphatase, indicating the absence of end-groups. The Table shows the results of the reaction of adenosine (0.1M) with sodium trimetaphosphate  $(0.3\text{M}-\text{Na}_3\text{P}_3\text{O}_9)$  in NaOH (0.5M). The solution was heated under

reflux for 4.5 hr., and then fractionated on a column of Dowex  $1 \times 2$  (formate) in 0.2m formic acid. The proportion of 3'- to 2'- isomers is reminiscent of that obtained from the hydrolysis of a 2', 3'- cyclic phosphate, which is a reasonable intermediate.

	Relative yields of monophosphate isomers (%)			Total conversion
				of nucleoside
Nucleoside	5'	2'	3′	(%)
Adenosine	0	42	58	31
Deoxyadenosine	37		63	2

Only 2% conversion of deoxyadenosine into nucleotide was observed, suggesting that a specific interaction of the trimetaphosphate ion with the *cis-vicinal* configuration of the ribonucleoside is involved.¹ In the absence of base, no reaction with adenosine could be detected.
