10 **ABSTRACT**

11 In this paper, we report an in-situ synthesis of silver supported on cobalt oxide (Ag/Co<sub>3</sub>O<sub>4</sub>)  
12 nanoparticles (NPs) and studied the catalytic activity of this material as an eco-friendly,  
13 simple, recyclable and efficient catalyst for one-pot photocatalytic oxidation of aromatic  
14 alcohols. Ag nanoparticles with the sizes of 2–5 nm supported on spherical Co<sub>3</sub>O<sub>4</sub> with the  
15 radius between 40 and 60 nm were synthesized by homogeneous chemical precipitation  
16 followed by hydrothermal heating. The as-synthesized catalyst was thoroughly characterized  
17 by powder X-ray diffraction (XRD), scanning electron microscopy (SEM), energy-dispersive  
18 X-ray spectroscopy (EDX), elemental mapping, transmission electron microscopy (TEM), X-  
19 ray photoelectron spectroscopy (XPS), Fourier transform infrared spectroscopy (FTIR),  
20 thermogravimetric analysis (TGA) and N<sub>2</sub> adsorption-desorption isotherm (BET) analysis. It  
21 was observed that the catalysts with 1 wt% of silver loading shows high activity and  
22 selectivity toward the target aldehyde product. The effects of different reaction parameters  
23 such as reaction time, oxidant and solvent were investigated and studied in detail. The  
24 synergistic effect between the surface Ag NPs and Co<sub>3</sub>O<sub>4</sub> nanospheres plays a vital role  
25 toward very high catalytic activity.

## 2 **1. Introduction**

3 During last few decades, preparation and characterization of inorganic materials with  
4 nanosized dimensions and morphological specificity has become highly important and  
5 received a great deal of interest in various science and technology fields [1-7]. Recently,  
6 nanomaterials have attracted much research attention due to their applications in medicine,  
7 biology, electronics and chemical industries [8-11]. Nanostructured materials with low  
8 density and high specific surface area are considered suitable candidates for a variety of  
9 applications. Their significantly enhanced activity can be attributed to their highly accessible  
10 surface area with a large number of active sites [12,13]. It was observed that nanomaterials  
11 doped with another metal boost their catalytic efficiency to great extent due to synergistic  
12 effects [14]. Noble metal nanomaterials such as silver and gold have shown tremendous  
13 potential for applications in various fields including catalysis [15, 16]. Their controlled effect  
14 as dopants on various transition and nontransition metal oxide supports, such as titania,  
15 alumina, and silica, has provided a new aspect to their utility in catalytic science and  
16 technology [17-21]. Several green methods for the synthesis of Ag nanoparticles (NPs) are  
17 known [22]. Synthesis methods for supported transition metal oxide nanomaterials such as  
18 sonochemical methods, microwave irradiation, and vapor deposition have been studied and  
19 they have their own advantages and disadvantages. Despite significant research efforts,  
20 controlled and easy synthesis of Ag-supported  $\text{Co}_3\text{O}_4$  nanomaterials in solution is still highly  
21 challenging. Development of a facile method for the synthesis of Ag-supported  $\text{Co}_3\text{O}_4$   
22 nanomaterials with desired size, shape and morphology is still considered a challenging task.  
23 Huang *et al* has synthesized Ag-decorated  $\text{Co}_3\text{O}_4$  nanosheets on nickel foam *via* a  
24 hydrothermal method and it was found that the morphology of  $\text{Co}_3\text{O}_4$  can be controlled by  
25 adjusting the hydrothermal time and the concentration of reactants [5]. Herein, we report a

1 simple and reproducible preparation method for the synthesis of silver supported on  $\text{Co}_3\text{O}_4$   
2 spinel nanoparticles *via* a hydrothermal synthesis followed by calcination. Silver supported  
3 on  $\text{Co}_3\text{O}_4$  nanoparticles was synthesized by an in-situ synthesis procedure and it was found  
4 that the in-situ synthesis procedure is better than the impregnation method for the  
5 photocatalytic oxidation of alcohol. The added advantage of the synthesis procedure is that it  
6 can be applied on a large scale synthesis (up to 10 g).

7 Oxidation of alcohols is one of the most important transformations in synthetic organic  
8 chemistry [23, 24]. The oxidation products are known to be essential intermediates in the  
9 manufacture of agrochemicals, fine chemicals, pharmaceuticals and high-value commodity  
10 chemicals [25, 26]. With a growing concern with economic and environmental acceptability,  
11 researchers across the world are devoting much effort to accomplish such oxidation with  
12 oxygen or hydrogen peroxides [27-30]. Several excellent catalysts have been developed for  
13 environmentally benign oxidation of alcohols to carbonyl compounds [31]. Recently,  
14 photocatalytic oxidation of aromatic alcohols where aldehyde was obtained as a major  
15 product using a nanostructured catalyst has been of interest among researchers [32-35]. In  
16 particular, Jing *et al.* have reported on the use of  $\text{Bi}_2\text{MoO}_6$  spheres for the photocatalytic  
17 oxidation of benzyl alcohol [36]. Zhang *et al.* have reported on the photocatalytic oxidation  
18 of benzyl alcohol over  $\text{TiO}_2$  nanorods loaded with Au-Pt nanoparticles. They have  
19 immobilized the Au-Pt nanoparticles on  $\text{TiO}_2$  nanorods where photocatalytic activity for  
20 benzyl alcohol was obtained under visible light irradiation [37]. Perovskite materials were  
21 also studied for the selective photocatalytic oxidation of benzylic alcohols [38]. Ziarati *et al.*  
22 has synthesized graphene highly wrapped yolk@shell  $\text{TiO}_2$  (G-HW-Y@S- $\text{TiO}_2$ )  
23 nanomaterials for photocatalytic performance in visible light oxidation of aromatic alcohols  
24 and found that the selectivity of aldehyde was intact even after 12 h of reaction [39]. Ding *et*  
25 *al.* has reported graphitic  $\text{C}_3\text{N}_4$ -based polymers for photocatalytic oxidation of aromatic

1 alcohols. The study reveals that vacancy defect in the semiconductors plays an important role  
2 in enhancing the photocatalytic activity of semiconductor photocatalysts [40]. Qiu *et al* has  
3 studied noble metal nanoparticle-functionalized Zr-metal organic frameworks for aromatic  
4 oxidation of alcohols to aldehydes. It was observed that the photocatalytic oxidation of  
5 aromatic alcohols to aldehydes was enhanced over Au/UiO-66-NH<sub>2</sub> or Au/UiO-66  
6 photocatalyst, but the activity was suppressed over Pt loading [41]. All the materials have  
7 their own advantage and disadvantage. Moreover all the reported process uses an atom-  
8 economic catalyst system that utilizes available green and clean renewable solar energy  
9 which is favorable from an environmental standpoint. However some suffers from multi-step  
10 catalyst synthesis procedure, long reaction run, low conversion or low selectivity. Therefore,  
11 we herein report a simple single step procedure for the synthesis of silver supported on Co<sub>3</sub>O<sub>4</sub>  
12 spinel nanoparticles and studied its activity for environmentally friendly photocatalytic  
13 oxidation of aromatic alcohols. It was found that the synthesized nanomaterials is highly  
14 active for photocatalytic oxidation of aromatic alcohols and a small loading of silver is  
15 sufficient for high conversion and selectivity towards the target product aldehyde.

## 16 **2. Experimental**

### 17 **2.1 Catalyst preparation**

18 A spherical Ag/Co<sub>3</sub>O<sub>4</sub> spinel nanoparticles catalyst was prepared by surfactant-  
19 assisted hydrothermal method through the modification of a synthesis method  
20 previously reported by us [42]. The benefit of this procedure is that the catalyst can be  
21 synthesized on a large scale (up to 10 g) and in a highly reproducible manner. First,  
22 11.96 g of Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O and 0.16 g of AgNO<sub>3</sub> were dissolved separately in a  
23 minimum volume of distilled water. The resultant solutions were then mixed and  
24 stirred magnetically. Subsequently, 1.8 g CTAB dissolved in a mixture of 50 ml  
25 distilled water and 2 ml ethanol was added to the mixed solution. Through the gradual

1 addition of an ammonia solution, the pH of the solution was adjusted to 8 followed by  
2 the addition of 0.1 g of hydrazine and was finally stirred for another 20 min at which  
3 point the mixture turned into a homogeneous solution with a jet black color. Then, the  
4 precursor solution was transferred into a 50 mL autoclave with a Teflon liner and was  
5 held at 180 °C for 12 h. After washing with excess H<sub>2</sub>O and ethanol, the obtained  
6 sample was dried at 80 °C for 12 h. The as-obtained precursor powder was then  
7 calcined in a quartz reactor inside a tubular resistance furnace for 4 h at 550 °C to  
8 obtain the Ag/Co<sub>3</sub>O<sub>4</sub> spinel nanoparticles catalyst powder. The catalyst was also  
9 prepared by the impregnation method and the coprecipitation method. The loading of  
10 the silver nanoparticles was confirmed by inductively coupled plasma atomic emission  
11 spectrometer analysis (ICP-AES).

## 12 **2.2 Photocatalytic oxidation of alcohol**

13 Liquid phase photocatalytic alcohol oxidation was performed in a 100 mL quartz  
14 reactor equipped with magnetic stirrer with O<sub>2</sub> atmosphere under simulated sunlight  
15 irradiation. The 20 mg of photocatalyst was suspended in 10 ml acetonitrile, used as a  
16 solvent, followed by the addition of aromatic alcohol (1 mmol). The reaction was  
17 performed under the irradiation of a 300 W Xe lamp without UV and IR cut-off filters.  
18 At regular intervals of the photooxidation reaction, a small portion of the sample was  
19 withdrawn from the reaction mixture for analysis. The conversion and selectivity of  
20 the product were calculated by gas chromatography (GC, Agilent 7890) using  
21 methylbenzene as an external standard.

## 22 **3. Results and discussion**

23 <Fig. 1>

24 The phase purity and crystalline structure of Ag/Co<sub>3</sub>O<sub>4</sub> was investigated using powder  
25 X-ray-diffraction (PXRD) analysis. The powder XRD patterns of the synthesized

1 silver supported by  $\text{Co}_3\text{O}_4$  nanoparticles are presented in Fig. 1. The peaks at  $2\theta$  of  
2  $19.0^\circ$ ,  $31.2^\circ$ ,  $36.9^\circ$ ,  $44.8^\circ$ ,  $55.7^\circ$ ,  $59.3^\circ$ ,  $65.3^\circ$ ,  $74.1^\circ$  and  $77.3^\circ$  confirmed the formation  
3 of the face-centered cubic structured  $\text{Co}_3\text{O}_4$  nanoparticles. The diffraction pattern  
4 matched the reported  $\text{Co}_3\text{O}_4$  patterns well (JCPDS 78-1969). No crystalline phase of  
5 metallic Ag was detected by XRD for 0.5% and 1% Ag/ $\text{Co}_3\text{O}_4$  (Fig. 1(a and b)),  
6 indicating that the very small Ag-crystallites are highly dispersed over the  $\text{Co}_3\text{O}_4$   
7 support. Moreover, in addition to the diffraction peaks of  $\text{Co}_3\text{O}_4$ , we observed an  
8 additional peak at  $2\theta$  of  $38.1^\circ$  corresponding to the metallic Ag crystal faces of (111)  
9 which coincide well with the literature values (JCPDS File no. 89-3722) for 1.5%  
10 Ag/ $\text{Co}_3\text{O}_4$  and the spent catalyst (Figs. 1(c,d)). No impurity peaks were observed,  
11 indicating the high purity of the nanoparticles. No change in the XRD pattern of the  
12 spent catalyst was observed even after five cycles of reuse (Fig. 1(d)).

13 <Fig. 2>

14 The morphology of the as-prepared Ag/  $\text{Co}_3\text{O}_4$  catalysts was determined by scanning  
15 electron microscopy. The representative SEM images of the fresh catalyst show an almost  
16 spherical shape with the size of 40-60 nm (Figs. 2(a,b). The EDS pattern showed only the  
17 presence of cobalt, silver and oxygen and no impurities could be observed in the spectra (Fig.  
18 2(d)). The dispersion of silver on the nanocrystalline  $\text{Co}_3\text{O}_4$  was confirmed by the elemental  
19 mapping of the catalyst that found a homogenous distribution of Ag on the nanocrystalline  
20  $\text{Co}_3\text{O}_4$  support (Fig. 3). The spent catalyst also showed a homogenous distribution (Fig. S2 in  
21 ESI).

22 <Fig. 3>

23 <Fig. 4>

1 High-resolution transmission electron microscopy (HRTEM) analysis was carried out to  
2 examine the particle size and distribution of the silver nanoparticles on nanocrystalline  $\text{Co}_3\text{O}_4$   
3 (Fig. 4). The TEM image of  $\text{Co}_3\text{O}_4$  nanoparticles showed an almost spherical shape with the  
4 size of 40-60 nm. The average particle size of silver nanoparticles was observed in the range  
5 of 2–5 nm. The spacing of the lattice fringes was found to be 0.28 nm and 0.23 nm, possibly  
6 due to the (220) plane of  $\text{Co}_3\text{O}_4$  and the (111) plane of metallic Ag, respectively.  
7 Furthermore, the TEM image of the spent catalyst (Fig. S1 in ESI) shows almost the same  
8 shape and size even after five reuses. The corresponding particle size distribution histogram  
9 of the Ag nanoparticles showed a very narrow particle size distribution with the sizes  
10 between 2 and 5 nm which is in good agreement with the values obtained from the XRD data  
11 (Fig. S1 in ESI).

12 <Fig. 5>

13 The metallic state and the surface composition of the synthesized nanospheres were  
14 investigated by X-ray photoelectron spectroscopy (XPS). As shown in Fig. 5, the XPS  
15 spectrum of the samples reveals the presence of the Ag, Co, and O elements. The Co 2p  
16 spectrum of the fresh catalyst could be fitted to two spin-orbit doublets that are characteristic  
17 of  $\text{Co}^{2+}$  and  $\text{Co}^{3+}$  and two shake-up satellites. The two main peaks at 780.1 and 795.2 eV with  
18 a characteristic peak difference of 15.1 eV can be assigned to the  $2p_{3/2}$  and  $2p_{1/2}$  of  $\text{Co}^{2+}$  and  
19  $\text{Co}^{3+}$ , respectively (Fig. 5(a))[43]. The O 1s spectra of the fresh catalyst could be  
20 deconvoluted to three different oxygen contribution peaks labeled as  $\text{O}_{\text{latt}}$ ,  $\text{O}_{\text{hyd}}$  and  $\text{O}_{\text{ads}}$  at  
21 the binding energies of 529.8, 531.8, and 533.2 eV, corresponding to the lattice oxygen,  
22 hydroxyl oxygen and physically adsorbed oxygen ( $\text{O}_{\text{ads}}$ ), respectively (Fig. 5(b)). The high-  
23 resolution spectrum of the silver nanoparticles contained two prominent Ag  $3d_{5/2}$  and Ag  $3d_{3/2}$   
24 peaks at the binding energies of 368.2 eV and 374.1 eV, corresponding to metallic  $\text{Ag}^0$  and  
25 the two small peaks at 368.6 and 374.6 eV are ascribed to the  $\text{Ag}^+$  species (Fig. 5(c)) [44].

1 <Fig. 6>

2 The specific surface area, pore volume and pore diameter play important roles in the  
3 catalytic activity. The textural properties of the synthesized Ag/Co<sub>3</sub>O<sub>4</sub> nanoparticles  
4 were investigated using nitrogen adsorption and desorption isotherms (Fig. 6). The N<sub>2</sub>  
5 adsorption–desorption isotherms of the samples show typical IV-type isotherms with  
6 high pore volume and specific surface area. The BET surface areas of the as-  
7 synthesized nanoparticles and the spent catalyst were measured to be 46.23 and 40.74  
8 m<sup>2</sup>g<sup>-1</sup>, respectively (Fig. 6(a)). The Barrett-Joyner-Halenda (BJH) pore size  
9 distribution indicated that most of the pores are in the range from 2 to 15 nm (Fig.  
10 6(b)). Table 1 summarizes the structural and the textural properties such as the surface  
11 area, pore volume and pore size derived from the nitrogen adsorption and desorption  
12 isotherms of the prepared nanomaterials.

13 <Table 1>

14 <Fig. 7>

15 The surface-coordination of the organic surfactant molecules on the uncalcined nanoparticles  
16 was studied by FTIR analysis (Fig. 7). A comparison of the FTIR spectrum of a dried  
17 uncalcined nanoparticles precursor with that of the calcined nanoparticles was performed, not  
18 only confirming the presence of the surfactant molecules but also revealing the nature of the  
19 interaction of the surfactant molecules with the metal oxide surface. For dried uncalcined  
20 nanoparticles, the O-H group stretching vibration was observed at 3472 cm<sup>-1</sup>. The peaks at  
21 1632 cm<sup>-1</sup> were attributed to the C=O stretching vibration and the peaks at 1382 and 1109  
22 cm<sup>-1</sup> were due to the C–N vibrational mode, confirming the presence of CTAB in the  
23 precursor (Fig. 7(a)). After the sample was washed and calcined, the peak intensity of the  
24 calcined nanoparticle decreased with two additional peaks observed at 674 and 569 cm<sup>-1</sup> that

1 can be attributed to the characteristic peaks of the metal oxide (Co–O), confirming the  
2 removal of the surfactant during the calcination (Fig. 7(b)).

3 <Fig. 8>

4 The TGA curve (Fig. 8) shows a two-step decomposition pathway. The weight loss of 4.04%  
5 in the first step (30-200°C) is due to the removal of the physically adsorbed moisture in the  
6 precursor. The weight loss of 32.16% in the second step (200-520°C) indicated the  
7 combustion of CTAB from the surface and the subsequent conversion of Ag/Co(OH)<sub>3</sub> to  
8 Ag/Co<sub>3</sub>O<sub>4</sub>.

9 The UV-visible light absorption properties of the composites were measured by UV-Vis DRS  
10 spectroscopy (Fig. S3(a) in ESI). The Ag/Co<sub>3</sub>O<sub>4</sub> composites shows a wide absorption range  
11 over the visible light region. Band gaps were calculated using the Tauc plot and the band gap  
12 of Ag/Co<sub>3</sub>O<sub>4</sub> was found to be 1.47 eV (Fig. S3(b) in ESI). Photoluminescence (PL) was also  
13 investigated at room temperature, and the Ag/Co<sub>3</sub>O<sub>4</sub> composites were excited at the  
14 wavelength of 310 nm and the characteristic green emission peak was observed at 492 nm  
15 (Fig. S3(c) in ESI).

### 16 3.2 Catalytic activity

17 We have explored the catalytic activity of the synthesized nanomaterial for photocatalytic  
18 alcohol oxidation. Various reaction parameters such as the solvent, time and catalyst weight,  
19 were optimized in order to obtain the best result, with benzyl alcohols chosen as the standard  
20 substrate. The photocatalytic oxidation experiment was conducted under different solvents  
21 *viz.* acetonitrile, dimethyl carbonate, trifluorotoluene, tributyl phosphate and water. It was  
22 apparent from the optimization experiments that acetonitrile was the best and most suitable  
23 solvent for the present photocatalytic reaction (Table 2). Table 3 summarizes the optimized

1 parameters of various catalyst for the photocatalytic alcohol oxidation where aldehyde was  
2 detected as the major product with benzoic acid as a minor product.

3 **<Table 2>**

4 To explore the individual role of the oxide, we have performed the catalytic activity  
5 measurements in the presence of commercially available Ag and  $\text{Co}_3\text{O}_4$  and found a  
6 negligible amount of activity. By contrast, when the reaction was performed with the  
7 commercially available Ag/ $\text{Co}_3\text{O}_4$  catalyst, we find an increase in the conversion of the  
8 alcohol but the activity of the reported synthesized silver supported on  $\text{Co}_3\text{O}_4$  is still not  
9 comparable. This can be attributed to the small particular size and high surface area which  
10 leads to a high dispersion of catalyst compared to the commercial catalyst, which has an  
11 irregular shape and large particle size, leading to the limited accessibility of the catalyst for  
12 the catalytic reaction. By contrast, the synthesized nanocatalyst consists of highly dispersed  
13 nanospheres, leading to more exposed active surface sites for the catalytic reaction to occur.  
14 Again, when the reaction was performed in absence of the catalyst and in the presence of the  
15 oxidant, we observed a negligible conversion amount, underscoring the vital role of the  
16 catalyst in the photocatalytic oxidation reaction of alcohol and for the selectivity to  
17 benzaldehyde.

18 **<Table 3>**

19 Taking into account this optimized parameter, we explored the scope of the reaction for  
20 various substituted alcohols. It was observed that the substituted electron-donating group  
21 facilitates the oxidation reaction, whereas the electron-withdrawing group retards the  
22 formation of the aldehyde (Table 4). When the substrate is an electron-donating group such  
23 as  $-\text{CH}_3$  and  $-\text{OCH}_3$ , it facilitates the oxidation reaction with the reaction completed in a short  
24 time with a somewhat high conversion. Whereas when the substrate is an electron-

1 withdrawing group such as Br and F. aldehyde formation is hampered, so that the reaction  
2 requires a long time to complete. The conversion and selectivity are not so much affected,  
3 however, we have drawn the conclusion with respect to time. Based on the results and  
4 previously reported methods, we proposed a possible mechanism as shown in Scheme 1.  
5 Under the irradiation of visible light, the photogenerated carriers were produced, the excited  
6 electrons migrated from the valence band (VB) of  $\text{Co}_3\text{O}_4$  to the conduction band (CB). At the  
7 same time, the electrons from the conduction band of  $\text{Co}_3\text{O}_4$  migrated to the Ag nanoparticles  
8 where the surface plasmon resonance (SPR) activity of Ag also plays a vital role; the Ag  
9 nanoparticle also absorbs photons producing electron-hole pairs due to SPR, leading to the  
10 prevention of the electron-hole pair recombination and an excellent photocatalytic activity.  
11 The CB energy level of 0.50 V is more positive than the potential of  $\text{O}_2/\text{O}_2^-$  which is -0.046  
12 V so that the electrons transfers to Ag when the  $\text{O}_2$  is reduced to ' $\text{O}_2^-$ ' which in turns produces  
13 the superoxide radical ( $\cdot\text{OOH}$ ). The superoxide radical converts the activated alcohol cation  
14 radicals produced by the action of  $\text{h}^+$  holes in the VB of  $\text{Co}_3\text{O}_4$  on the alcohol to aldehyde  
15 [40,45]. A comparison between the present catalyst and some of the previously reported  
16 catalytic methods for the photocatalytic oxidation of benzyl alcohol to benzaldehyde are  
17 summarized in table S1 in ESI.

18

**<Table 4>**

19 After each catalytic run and completion of the reaction, the solid catalyst was filtered from  
20 the reaction mixture and washed with ethanol, and reused for multiple cycles to check the  
21 stability of the catalyst (Fig. 9). Negligible change in the activity of the recovered catalyst  
22 after 5 consecutive cycle was observed, indicating the true heterogeneity of the catalyst  
23 (Table 2, entry 7). The SEM image of the spent catalyst showed almost similar sizes and  
24 shapes to that of the fresh catalyst (Fig. 2(c)). Moreover, a negligible amount of leaching of  
25 the metal was detected during the reaction (concentrations of both metals were  $<2$  ppb).

1 <Fig. 9>

## 2 **4. Conclusions**

3 In summary, we have presented a facile and simple surfactant-assisted synthesis of silver  
4 nanoparticles supported on the  $\text{Co}_3\text{O}_4$  nanoparticles *via* hydrothermal heating followed by  
5 calcination. The methodology adopted for the synthesis of the supported nanoparticle is  
6 simple and can be readily utilized for large-scale synthesis. Initial characterization shows that  
7 the nanoparticle is spherical in shape with the size of 40-60 nm. The synthesized nanoparticle  
8 was evaluated as a catalyst for one-pot photocatalytic oxidation of alcohol to aldehyde. The  
9 catalyst with 1% Ag loading was found to have the optimum loading for the photocatalytic  
10 alcohol oxidation to aldehyde with the high conversion of 76% and aldehyde selectivity of  
11 >99% within 8 h of reaction time.

## 12 **Acknowledgements**

**Highlights**

- One-pot hydrothermal synthesis of silver supported cobalt oxide.
- 2–5 nm Ag-nanoparticles supported on 40–60 nm  $\text{Co}_3\text{O}_4$  nanosphere.
- Room temperature photocatalytic oxidation of alcohol to aldehyde.
- Alcohol conversion of 76% with 99% selectivity of aldehyde.
