Abstract:

Herein, we report a simple and metal-free method for the synthesis of *N*-azine sulfoximines by the nucleophilic substitution of azine *N*-oxides with *NH*-sulfoximines. The present method works at room temperature with wide functional group compatibility and gives several unprecedented *N*-azine sulfoximines. The reaction conditions also found suitable with enantiopure substrates and furnished products without any racemisation. It also finds an application in the sulfoximination of azine based functional molecules such as 2,2'-bipyridine, 1,10-phenanthroline and quinine.

Introduction:

Sulfoximines are well-known for their application as chiral auxiliaries^{1a-c} and ligands^{1d-g} in asymmetric synthesis, as well as building blocks in pseudopeptides.² However, in recent years, their use in drug discovery have attracted the attention of medicinal chemists.³ In drug discovery, this moiety has been used for improving specificity,⁴ stability/oral bio-availability⁵ and reducing undesired toxicity.⁶ In addition, sulfoximines have also been used as bio-isosters for several functional moieties such as heterocyclic amidine,^{5,7} sulfones⁸ and secondary hydroxyl groups,⁹ as well as stable transition-state analogue inhibitors.¹⁰ Keeping in view the importance of sulfoximines in drug discovery and catalysis, several groups world-wide are interested in the synthesis of sulfoximines,^{11,12} but only few reports are available for *N*-substituted derivatives,^{1b,13} which involved either traditional transition-metal catalysed cross-coupling (Scheme 1, approach a) ^{1b,13a-d} or cross dehydrogenative coupling methods (Scheme 1, approach b-c).^{13e,f}

Our constant interest in the functionalization of electron–deficient system¹⁴ motivated us to develop a simple method for the sulfoximination of electron–deficient heteroarenes. Initially, we tried the coupling of *iso*-quinoline with *N*-chlorosulfoximine in the presence of iron salt.^{14a} Unfortunately, no reaction was observed (Scheme 1, approach e, path A). We rationalized that the attempted reactions generated sulfoximinyl radical cations from *N*chlorosulfoximine,¹⁵ which represents an electron-deficient system and coupling between two electron-deficient systems might not be possible.¹⁵ In this direction, Londregan *et al.* established a PyBroP (bromotripyrrolidinophosphonium hexafluorophosphate) mediated method for the functionalization of electron-deficient heteroarenes with various nucleophiles (amine, phenol, sulfonamide, malonate, pyridine, thiol, silyl ketene acetal)¹⁶ which has become a remarkable strategy for constructing a variety of carbon–carbon or carbon-heteroatom bonds under metal-free conditions (Scheme 1, approach d).¹⁶ Considering the nucleophilic nature of *NH*-sulfoximines, we envisioned that the same approach could be explored for the sulfoximination of electron-deficient heteroarenes. Here, we have successfully applied a precedented method for the sulfoximination of azines through azine *N*-oxides in the presence of the *N-O* activating agent, PyBroP (Scheme 1, approach e, path B). The method works well with substituted and unsubstituted quinolines, isoquinolines and pyridines, and gives the corresponding *N*-azine sulfoximines in good to excellent yields.

Scheme 1. Previous and present reports

Results and discussion:

Our investigation started with test substrates isoquinoline-*N*-oxide **1a** and racemic *S*methyl-*S*-phenylsulfoximine **2a** in the presence of PyBroP as *N*-oxide activating agent using the conditions reported by Londregan *et al*,^{16b,c} which successfully gave desired coupled product **3aa** in a yield of 87%. After this success, the applicability of sulfoximines was examined, and all the results are given in Scheme 2. Various sulfoximines efficiently coupled with isoquinoline-*N*-oxide **1a** and gave corresponding coupled products **3aa-ao** in good to excellent yields.

Scheme 2. Addition of various sulfoximines to isoquinoline-N-oxide^a

^aReaction conditions: All reactions were conducted at 0.2 M concentration with **1a** (0.2 mmol, 1.0 equiv), **2** (0.26 mmol, 1.3 equiv), ^{*i*}Pr₂EtN (0.6 mmol, 3.0 equiv) and PyBroP (0.22 mmol, 1.1 equiv) at 25 °C for 15 h.

A series of alkyl aryl and diaryl sulfoximines containing electron-donating groups (OMe and Me) and electron-withdrawing groups (Br, Cl, F and NO₂) on the aryl ring underwent smooth reaction with isoquinoline-N-oxide 1a and gave the desired products (3ab-**3ah**) in good to high yields. The high C-1 regioselectivity as observed earlier, ^{16c,17} might be directed by LUMO electron density of the azine N-oxide. Sulfoximines with electrondonating groups on phenyl ring have shown slightly better yields than sulfoximines with electron-withdrawing groups. Cyclic and dialkyl sulfoximines, S,Stetramethylenesulfoximine, S.S-dimethylsulfoximine and S.S-dibutylsulfoximine also worked and afforded the corresponding products **3ai**, **3aj** and **3ak** in good yields. Sterically hindered S-methyl-S-naphthyl sulfoximine didn't give good results. To our delight, S-ethyl, S-propyl and S-butyl phenyl sulfoximines also furnished high yields of corresponding products **3am**, **3an** and **3ao**, respectively.

Further, this reaction was successfully extended to various pyridine- and quinoline-*N*-oxides (Scheme 3). Mostly, all substrates reacted smoothly and afforded the desired products in good yields. Pyridine-*N*-oxide gave a 1:1 mixture of separable 2- and 4-substituted products **4aa** and **4aa'** in an overall yield of 75%. Unfortunately, 2-methyl and 2,6-dimethyl pyridine-*N*-oxides were not good substrates for this transformation (**4ab** and **4ac**). However, 3-methylpyridine-*N*-oxide gave corresponding 2-subsituted products **4ad-4ae** with moderate to good yields On the other hand, 3-bromopyridine-*N*-oxide gave a separable mixture of 2- and 6-substituted products **4af** and **4af'** in the ratio of 2:1 in an overall yield of 42%. ^{16c,17} The 2-phenylpyridine-*N*-oxide afforded corresponding single regiomers **4ag** and **4ah** in a yields of 65% and 35%, respectively. Further, 2-bromo-4-chloropyridine-*N*-oxide furnished low yields (**4ai** and **4aj**).

Pyridine-*N*-oxides having electron-donating (*t*Bu) and electron-withdrawing (CN, CF_3 , NO₂) groups at the 4th position furnished the single regio-isomeric respective products

The Journal of Organic Chemistry

4ak-4ao in a yields of 75 %, 65%, 75%, 40% and 35%, respectively. Diazine-*N*-oxide such as pyrazine-*N*-oxide was not found suitable substrate for this reaction. Gratifyingly, quinoline-*N*-oxides furnished single regio-isomeric products with good to excellent yields. The quinoline-*N*-oxide when subjected to a series of different alkyl aryl and dialkyl sulfoximines, the corresponding coupled products **4ca**, **4cb**, **4cc** and **4cd** were obtained in a yields of 80%, 69%, 65% and 53%, respectively. Similarly, 4-methylquinoline-*N*-oxide on coupling with various sulfoximines afforded coupled products **4ce**, **4cf** and **4cg** in yields of 72%, 60% and 65%, respectively. Furthermore, 5-bromoquinoline-*N*-oxide and 8-methoxyquinoline-*N*-oxide, when tried also furnished coupled products **4ch** and **4ci** in 63% and 70% yields, respectively. When 6-Bromoquinoline-*N*-oxide was employed in this reaction with *S*-methyl-*S*-phenylsulfoximine and *S*,*S*-dibutylsulfoximine, the corresponding products **4cj** and **4ck** were found in good yields of 70% and 60%, respectively. The *N*-methyl 8-aza indole-*N*-oxide did not undergo coupling.

^aReaction conditions: All reactions were conducted at 0.2 M concentration with 1 (0.2 mmol, 1.0 equiv), 2 (0.26 mmol, 1.3 equiv), iPr_2EtN (0.6 mmol, 3.0 equiv) and PyBroP (0.22 mmol, 1.1 equiv) at 25 °C for 15 h.

Considering the mildness of the reaction conditions, isoquinoline-*N*-oxide **1a**, was treated with enantiopure sulfoximine (*S*)-(+)-*S*-methyl-*S*-phenylsulfoximine, (Scheme 4), the corresponding product (*S*)-(-)-**3aa** was obtained in 85% yield with high enantiomeric excess

 (>99% ee, see SI), respectively suggested that chiral substrates are also tolerated under reaction conditions.

Scheme 4. Reaction with enantiopure sulfoximine^a

^aReaction conditions: Reaction was conducted at 0.1 M concentration with **1a** (0.2 mmol, 1.0 equiv), **2a** 0.26 mmol, 1.3 equiv), ^{*i*}Pr₂EtN (0.6 mmol, 3.0 equiv) and PyBroP (0.22 mmol, 1.1 equiv) at 25 ^oC.

After exploring the feasibility of the present method with various substrates, its application towards the diversification of azine-based functional molecules were also explored. Azine-based functional molecules, such as 1,10-phenanthroline and 2,2'-bipyridine, are well known ligands and in many instances their substituted versions provide additional advantages in terms of reactivity and selectivity.¹⁸ On the other hand, sulfoximines are also well-known for their application as chiral auxiliaries^{1a-c} and ligands,^{1d-g} and sulfoximination of the above mentioned ligands may provide some advantages. Towards this end, sulfoximidoyl containing 1,10-phenanthroline **6aa** and 2,2'-bipyridine **6ab** were successfully synthesized on reaction with *S*-methyl-*S*-phenylsulfoximine (Scheme 5).

Scheme 5. Sulfoximination of ligands^a

^aReaction conditions: All reactions were conducted at 0.1 M concentration with **5a** or **5b** (0.2 mmol, 1.0 equiv), **2a** (0.26 mmol, 1.3 equiv), $^{\prime}Pr_{2}EtN$ (0.6 mmol, 3.0 equiv) and PyBroP (0.22 mmol, 1.1 equiv) at 25 $^{\circ}C$.

Furthermore, a notable example for the present method is the direct sulfoximination of quinine. The reaction of quinine analogue **7a** with racemic *S*-methyl-*S*-phenylsulfoximine **2a** (Scheme 6), provided the corresponding coupled product **8aa** as an unseparable diasteromeric mixture in a 1:1.2 ratio (predicted through NMR). The sulfoximination of azine based functional molecules proved the utility of the present method in the functionalization and diversification.

Scheme 6. Sulfoximination of quinine^a

^aReaction conditions: All reactions were conducted at 0.1 M concentration with **7a** (0.15 mmol, 1.0 equiv), **2a** (0.195 mmol, 1.3 equiv), [/]Pr₂EtN (0.45 mmol, 3.0 equiv) and PyBroP (0.165 mmol, 1.1 equiv) at 25 °C.

Conclusions:

In summary, we have developed a nucleophilic substitution reaction of azine *N*-oxides with sulfoximines. The present metal-free method provides a simple and mild approach for the synthesis of *N*-azine sulfoximines. This protocol works very well with various azines, such as substituted and unsubstituted isoquinoline, pyridine and quinolines and gives a diverse range of several novel and unprecedented *N*-azine sulfoximines. This reaction proceeds at room temperature, operationally simple, and has broad functional group compatibility and substrate scope. Moreover, by utilizing the present method, direct sulfoximination of functional molecules, such as 1,10-phenanthroline, 2,2'-bipyridine and quinine was also achieved.

EXPERIMENTAL SECTION:

General Information:

All the reactions were performed under nitrogen atmosphere. Analytical thin layer chromatography was performed using TLC pre-coated silica gel 60 F₂₅₄ (20 x 20 cm). TLC plates were visualized by exposing UV light. Organic solvents were concentrated by rotary evaporation. Column chromatography was performed on flash silica gel 230-400 mesh size and ethyl acetate/hexane mixture used for elution. Melting points were recorded on melting point instrument and are uncorrected. ¹H NMR (400 MHz or 500 MHz) and ¹³C NMR (101 MHz or 126 MHz) recorded on FT-NMR instruments. Chemical shift data for protons are reported in parts per million (ppm, scale) downfield from tetramethylsilane and are referenced to the residual proton in the NMR solvent (CDCl₃: δ 7.26). The coupling constant (*J*) are in Hz. ESI-MS and HRMS spectra were recorded on LC-Q-TOF machines. FT-IR was recorded in chloroform using NaCl plate. Optical rotations were measured at room temperature in 10 cm cells. Analytical HPLC was performed using a chiral stationary phase (flow rate: 1.0 mL/min, column type and eluent is given for the corresponding compound) and UV detection ($\lambda = 210$ nm or 254 nm) at 20 °C.

General procedure for the preparation of sulfoximines:^{19,20}

Step-I. Oxidation of sulfides to sulfoxides: To a stirred solution of $CuBr_2$ (0.05 equiv) and sulfide (1.0 equiv) in CH₃CN (2.0 mL/1mmol) was added 70% *t*-BuOOH (in water, 5.0 equiv). The reaction mixture was heated to reflux and the progress was monitored by TLC until all sulfide was found consumed. After completion, CH₃CN was evaporated and the crude mixture was washed with NaHCO₃ and extracted with ethyl acetate. The ethyl acetate was evaporated and the crude sulfoxides were subsequently used for the imination reaction.

Step-II. Imination of sulfoxides: A solution of crude sulfoxide (1.0 equiv) and sodium azide (1.2 equiv) in CHCl₃ (~8-10 mL for 5 mmol of sulfoxide) was stirred in an oven-dried three-

necked round bottom flask equipped with a reflux condenser and an addition funnel. Concentrated sulphuric acid (~2.0 mL for 1.0 g of sulfoxide) was introduced over 5-10 minutes at 0 °C. The resulting mixture was slowly warmed up to 45 °C and the same temperature was maintained until nitrogen gas evolution subsides. The reaction was continued for an additional 12 h at 45 °C. The reaction mixture was cooled and the pastymass was dissolved with ice-water. The organic layer was decanted and the aqueous layer was washed with minimum amount of CHCl₃. The aqueous layer was made slightly alkaline using 20% NaOH solution and extracted with CHCl₃ (3 × 5 mL, for 5 mmol sulfoxide). The combined organic extracts were dried over Na₂SO₄. Solvent was filtered and evaporated under reduced pressure. The crude residue was purified using column chromatography on silica gel to afford the desired sulfoximines in good yields.

General procedure for the preparation of azine *N*-oxides:²¹ To a 0 °C solution of the appropriate azine in CH_2Cl_2 (0.5 M) is added *m*-CPBA (2.0 equiv) and the reaction is allowed to stir at room temperature overnight. The reaction mixture is diluted with CH_2Cl_2 and washed with aq. KOH (6N, 3x), the organic layer is dried over Na_2SO_4 and the solvent is evaporated under reduced pressure. The azine *N*-oxides are obtained as white solids and used without further purification.

Synthesis of 1,10-phenanthroline *N*-oxide (5a):²² Hydrogen peroxide (30%, 1.4 mL) was added into the solution of the phenanthroline (10 mmol) in acetic acid (10 mL). The reaction mixture was stirred at 70 °C for 72 h. The solvent was evaporated under vacuum, and the residue was basified with aqueous solution of sodium carbonate until pH = 9. The resulting mixture was extracted with chloroform (3x20 mL). The organic phase were combined and dried over anhydrous sodium sulphate, filtered and evaporated under vacuum. The residue was purified by flash chromatography (silica gel, EtOAc: methanol 8:1).

Synthesis of 2,2'-bipyridyl *N*-oxide (5b):²³ 2,2'-Bipyridine (1.248 g, 8.00 mmol) was added to a 50 mL round-bottomed flask with stir bar, followed by dissolution in trifluoroacetic acid (6.0 mL). This was cooled to room temperature, followed by slow addition of 30% H₂O₂ (1.2 mL, 12 mmol). Reaction was stirred at room temperature for 2 h, followed by addition of chloroform (25 mL). This was washed with 6M aqueous NaOH (3 x 10 mL), followed by back extraction of the combined aqueous phase with dichloromethane (4 x 20 mL). The combined organic phase was dried over MgSO4, followed by evaporation *in vacuo* to give oil. This was dried under vacuum overnight to obtain required compound as a white solid.

Synthesis of *N*-oxide quinine analogue (7a):

Step I: *O*-benzylation:²⁴ To a solution of quinine (4.0 g, 12.4 mmol) in DMF (40 mL) under nitrogen atmosphere, NaH (1.36 g, 57 % suspension in mineral oil, 32.3 mmol) was added and the resulted mixture was stirred at room temperature for 2 h. Then BnCl (1.56 mL, 13.6 mmol) was added dropwise *via* a syringe over 10 minutes. The resulting mixture was stirred overnight. After the starting material was completely consumed, brine was added carefully (40 mL) and the resulting mixture was extracted with ethyl acetate (200 mL). The organic phase was washed with H₂O (5 x 100 mL), brine (100 mL) and dried over Na₂SO₄. The solvent was removed *in vacuo* to afford light yellow oil (5.1 g, 99%). This crude product was used for next reaction without further purification.

Step II: Oxidation:²⁵ At 0 °C, *m*-chloroperoxybenzoic acid (77%, 9.20 g, 37.5 mmol) was added in portions to a solution of above compound (4.89 g, 15.0 mmol) in chloroform (90 mL). The resulting suspension was allowed to warm to rt and stirred for 3 h at that temperature, during which time the reaction mixture became a clear yellow solution. The reaction was quenched with NaOH (aq) (10% in H₂O) until pH = 10. The resulting two-phase mixture was extracted with a mixed solvent of CHCl₃/MeOH (10/1, 50 mL×6). The organic phase was collected and the combined organic phase was dried over Na₂SO₄, filtered and

evaporated *in vacuo* to give the crude product as light yellow foam (5.30 g, 99% yield). This crude product was used in the next step without further purification.

Step III: Deoxygenation:²⁵ To the solution of above intermediate (5.30 g, 15.0 mmol) in acetone (60 mL) at 0 °C was added dropwise an aqueous solution of sulfurous acid (6% wt, 24 mL, 18 mmol). The resulting mixture was warmed to rt. The resulting mixture was stirred overnight. Then, the acetone was removed under vacuum and ammonium hydroxide was added to make the solution alkaline. Chloroform (50 mL×5) was used to extract the aqueous layer. The organic layers were combined, washed with brine (50 mL), dried over Na₂SO₄ and concentrated *in vacuo*. The residue was subjected to silica gel column chromatography (CHCl₃/MeOH = 20/1 + 1% Et₃N) to afford **7a** as a viscous liquid (4.51 g, 86% yield). ¹H NMR (400 MHz, CDCl₃) δ 8.75 (d, *J* = 9.6 Hz, 1H), 8.37 (d, *J* = 6.3 Hz, 1H), 7.46 – 7.28 (m, 8H), 5.78 (ddd, *J* = 17.5, 10.3, 7.6 Hz, 1H), 5.00 – 4.91 (m, 2H), 4.44 (dd, *J* = 29.2, 11.5 Hz, 2H), 3.90 (s, 3H), 3.27 (s, 1H), 3.14 (d, *J* = 5.0 Hz, 1H), 3.10 – 2.85 (m, 2H), 2.71 – 2.53 (m, 2H), 2.26 (s, 1H), 1.78 (dd, *J* = 33.4, 4.6 Hz, 3H), 1.49 (d, *J* = 7.8 Hz, 1H).

General procedure for the synthesis of *N*-azine sulfoximines: To a solution of sulfoximine (0.26 mmol, 1.3 equiv) in THF (1 mL) was added *i*-Pr₂EtN (0.6 mmol, 3 equiv) at room temperature. After stirring for 5 minutes, azine *N*-oxide (0.2 mmol, 1.0 equiv) and PyBroP (0.22 mmol, 1.1 equiv) were added sequentially. Then the reaction mixture was stirred at room temperature. After completion of the reaction (by TLC analysis), reaction mixture was diluted with CHCl₃ and washed with aqueous NaHCO₃ solution. The combined organic layers were dried over anhydrous NaSO₄, filtered and concentrated *in vacuo*. The crude compounds were purified through column chromatography and pure compounds were characterized by NMR and Mass analysis.
