Abstract: In dimethylformamide (DMF) superoxide ion (O_2^-) reacts with PhCHBrCHBrPh, MeCHBrCHBrMe, and CH_2BrCH_2Br (EDB) via 2:1 stoichiometry to produce PhCH(O), MeCH(O), and $CH_2(O)$, respectively. A similar oxygenation occurs when O2- and CH2BrCHBrCH2Cl (DBCP) are combined in 5:1 stoichiometry to yield two CH2(O) and one HOC(O)Oper substrate. The relative rates of reaction are in the order CH₂BrCH₂Br > PhCHBrCHBrPh > MeCHBrCHBrMe. On the basis of the reaction rates and the products, the initial step for each substrate is believed to be a nucleophilic attack on a bromo carbon (R₂CHBr) with displacement of Br and formation of R₂CHOO. Subsequent steps involve reduction by a second O₂- and a dioxetane closing on an adjacent C-X group.

The chemistry of O_2 - and its reactivity with a range of substrates (acids, electrophiles, oxidants, and activated secondary amines) have been discussed in several recent reviews.1-4 Although the chemical reactivity of superoxide ion (O2-) with monohalogenated hydrocarbons has been known since 1970, 5,6 studies of multihalogenated molecules have been limited to CH₂Br₂,⁷ chloromethanes and DDT,8 trichloromethyl substrates,9 and chloroalkenes. 10 The present report describes the reactivity of O_2 - with α -dibromoalkanes (PhCHBrCHBrPh, MeCH-BrCHBrMe, and CH₂BrCH₂Br) and an α -dibromo- β -chloroalkane (CH₂BrCHBrCH₂Cl) and characterizes the oxygenated products.

Experimental Section

Equipment. Conventional electrochemical instrumentation, cells, and electrodes were employed for the cyclic voltammetric and controlledpotential coulometric measurements, 11 and for the glassy carbon ringdisk kinetic measurements.9 The volatile reaction products were separated and identified with a Hewlett Packard Model 5880 gas chromatograph that was equipped with a 12.5-m glass capillary column and by mass spectrometry. A Vacuum Atmosphere Corp. inert atmosphere glovebox was used for the storage and preparation of solutions of tetramethylammonium superoxide.

Chemicals and Reagents. Burdick and Jackson "distilled in glass" UV-grade dimethylformamide was used as received for all of the experiments. Tetraethylammonium perchlorate (TEAP) from G. Frederick Smith Chemical Co. was dried in vacuo and used as the supporting electrolyte (0.1 M TEAP) in the electrochemical experiments. substrates PhCHBrCHBrPh (Aldrich), MeCHBrCHBrMe (Aldrich), CH₂BrCH₂Br (Aldrich), CH₂BrCHBrCH₂Cl (Shell), n-BuBr (Aldrich), and CH2ClCH2Cl (Aldrich) were assayed by gas chromatography and found to be >99% pure and were used without further purification. Solutions of O₂- were prepared either by controlled-potential reduction of dissolved O_2 or by dissolution of weighted amounts of tetramethylammonium superoxide $[(Me_4N)O_2]$.¹²

Scheme I

Methods. Addition of a quantity of substrate to known amounts of O_2^- (such that about 80% of the O_2^- was consumed) and subsequent measurement of the unreacted O2- concentration by anodic voltammetry provided the stoichiometric ratios for the quantity of O2- consumed per mole of substrate.

Measurements of the rate of reaction of superoxide ion with the various substrates were made with a rotated ring-disk electrode. The pseudo-first-order rate constants (k_1) were determined with the method that has been described by Albery and Hitchman¹³ and illustrated in a recent study of polyhalogenated hydrocarbons.5

The reaction products were characterized after stoichiometric amounts (at millimolar concentrations) of substrate and superoxide ion were combined. A negative voltage sweep provided a measure of the O₂ that was produced by the O2--substrate reaction. Aliquots of the reaction mixture were analyzed for halide ion by potentiometric titration with AgNO3 and for base by an aqueous pH titration with HCl. The product solution was diluted with H2O and extracted with diethyl ether and the latter analyzed by gas chromatography.

Results

Substrates with vicinal dibromo groups readily react with superoxide ion in aprotic solvents such as dimethylformamide to yield bromide ion, dioxygen, and 2 equiv of aldehyde. Table I summarizes the reaction stoichiometries for the combination of O₂-. with PhCHBrCHBrPh, MeCHBrCHBrMe, CH2BrCH2Br (EDB), CH₂BrCHBrCH₂Cl (DBCP), n-BuBr, and CH₂ClCH₂Cl and the products from the dibromo substrates. These results confirm that O₂- promotes a net dioxygenation of each substrate to give two aldehydes.

The rates of reaction for O₂- with PhCHBrCHBrPh and the other dibromo substrates have been determined by the rotated ring-disk technique (O₂ is reduced at the disk to O₂-, which reacts with substrate, and the unreacted O2- is oxidized at the ring electrode), 9,13 and the normalized pseudo-first-order rate constants

Table I. Stoichiometries and Kinetics for the Reaction of 0.1-5 mM O₂- with Multihalogenated Hydrocarbons in Dimethylformamide (0.1 M Tetraethylammonium Perchlorate) at 25 °C^a

substrate [S], 1-10 mM	O ₂ -· per S	X ⁻ released per S	O ₂ released per S	products per S	$\frac{k_1/[S],^b}{M^{-1} s^{-1}}$
PhCHBrCHBrPh	2.0 ± 0.1	2.0 ± 0.1	1.0 ± 0.1	2PhCH(O)	1000 ± 100
MeCHBrCHBrMe	2.0 ± 0.1	2.0 ± 0.1	1.0 ± 0.1	2MeCH(O)	160 ± 20
CH ₂ BrCH ₂ Br (EDB)	2.0 ± 0.1	2.0 ± 0.1	1.0 ± 0.1	2CH ₂ (O)	2000 • 200
CH ₂ BrCHBrCH ₂ Cl (DBCP)	5.0 ± 0.2	3.0 ± 0.2	2.0 ± 0.1	2CH ₂ (O), 1HOC(O)O ⁻	4000 ± 400
n-BuBr	1.0 ± 0.1	1.0 ± 0.1		2007	960 ± 100
CH ₂ ClCH ₂ Cl					24 ± 3

^a Stoichiometries determined for O_2^- -substrate reactions by titration of excess $(Me_4N)O_2$ (with voltammetric detection), for released Br^- and Cl^- by titration with $AgNO_3$; for released O_2 by negative scan voltammetry, and for organic products by ether extraction and capillary-column gas chromatography. ^b Pseudo-first-order rate constants, k_1 (normalized to unit substrate concentration [S]), were determined from measurements with a glassy carbon-glassy carbon ring-disk electrode that was rotated at 900 rpm.

are tabulated in Table I. For comparison the rate constants for *n*-BuBr and CH₂ClCH₂Cl also are included.

Discussion and Conclusions

The stoichiometric data in Table I for vicinal dibromoalkanes are consistent with an overall net chemical reaction that yields two aldehyde molecules from the nucleophilic displacement by superoxide ion of the two bromo groups (e.g., for PhCHBrCHBrPh).

$$PhCHBrCHBrPh + 2O_2^- \rightarrow 2PhCH(O) + 2Br^- + O_2 \qquad (1)$$

A reasonable mechanism for these dioxygenations is an initial nucleophilic attack of a bromo carbon followed by displacement of a bromide ion (Scheme I). A second O_2 - reduces the peroxyl radical to a peroxide, which attacks the adjacent bromo carbon to displace the second bromide ion and give a dioxetane intermediate that dissociates to two benzaldehyde molecules. The data of Table I indicate that MeCHBrCHBrMe and CH₂BrCH₂Br (EDB) react in an analogous manner to yield MeCH(O) and CH₂(O), respectively.

The initial reaction sequence for CH₂BrCHBrCH₂Cl (DBCP) probably is the same as for EDB to give two aldehydes.

$$CH_2BrCHBrCH_2Cl + 2O_2 \rightarrow CH_2(O) + CH_2ClCH(O) + 2Br^- + O_2$$
 (2)

The chloroacetaldehyde [CH₂ClCH(O)] rapidly reacts with three additional O_2^- ions to give bicarbonate ion and another formaldehyde (probably via another dioxethane intermediate to give a formate, which reacts with another O_2^- and residual water).

$$CH_2CICH(O) + 3O_2^{-} \xrightarrow{H_2O}$$

 $HOC(O)O^- + CH_2(O) + CI^- + O_2 + 0.5H_2O_2 + OH^- (3)$

The overall process for DBCP is the sum of reactions 2 and 3;

$$CH_2BrCHBrCH_2Cl + 5O_2^- \xrightarrow{H_2O} 2CH_2(O) + HOC(O)O^- + 2Br^- + Cl^- + 2O_2 + 0.5H_2O_2 + OH^- (4)$$

excess O_2^{-} induces the polymerization of the formaldehyde.

If the normalized pseudo-first-order rate constants $(k_1/[S])$ of Table 1 for EDB, DBCP, and n-BuBr are divided by the stoichiometric factors $(O_2^- \cdot \text{per } S)$ of the second column, values for the apparent second-order rate constants (k_2) result. For the three substrates these are essentially equal $(800 \text{ M}^{-1} \text{ s}^{-1} \text{ for DBCP}, 900 \text{ M}^{-1} \text{ s}^{-1}$ for n-BuBr, and $1000 \text{ M}^{-1} \text{ s}^{-1}$ for EDB), which is consistent with an initial nucleophilic attack for the methylenic bromo carbon as the rate-controlling step.

The formation of aldehydes from vicinal dihalo compounds via nucleophilic displacement by O_2 —and a dioxetane intermediate (Scheme I) is similar to the oxygenation of p,p'-DDT by superoxide. ¹⁰

$$(p\text{-ClPh})_2\text{CHCCl}_3 + 4\text{O}_2^{-1} \rightarrow (p\text{-ClPh})_2\text{C}(0) + \text{HOC}(0)\text{O}^{-1} + 3\text{Cl}^{-1} + \text{H}_2\text{O}_2 + 1.5\text{O}_2$$
 (5)

As is the case with polyhalogenated ethenes, ¹⁰ the initial nucleophilic addition of O_2^- to these substrates yields alkyl peroxyl radical intermediates (CH₂BrCH₂OO· in the case of EDB). The latter are effective initiators for the autoxidation of unsaturated fatty acids such as linoleic. ¹⁴ Hence, ingested vicinal dihalo compounds such as EDB and DBCH may react in vivo with superoxide to produce such peroxyl radical initiators for lipid peroxidation. This may represent the mechanism for the cytotoxicity of these pesticides.

In accord with previous reports, 8,15 the present results confirm that superoxide ion can be a useful and effective reagent for the degradation of halogenated pesticide wastes such as EDB and DBCP.
