On the basis of the xylose-inositol analogy, a series of permeant analogs of D-myo-inositol 1,4,5-trisphosphate (InsP₃) have been synthesized by various esterifications of the phosphate groups. Their ability to cross the cell membrane has been tested on vasopressin cells. Very fast liberation of calcium occurs when active analogs are introduced in the extracellular medium on intact cells. Membrane crossing as well as hydrolysis of the phosphate is very rapid using acyloxymethyl esterification of all the phosphate groups. The free compounds behave in the cell like InsP₃. One of the analogs

INTRODUCTION

The increasing knowledge of cellular mechanisms provides new opportunities for the development of molecular tools for the studies of biologic processes. Cellular response to an external stimulus is often the result of a cascade of events. Most of primary messengers bind to a specific G protein-coupled receptor (GPCR). It is then followed by a second series of signalling events such as calcium liberation. The discovery of this calcium signalling pathway has been a major event in cellular biology. [1-3] Even more interesting was the identification of the second messengers derived from the phosphoinositide pathway, in particular inositol 1,4,5-trisphosphate (InsP₃) 1. [4-6] This small molecule is formed by hydrolysis of a membrane-anchored phosphoinositide (PIP₃) by a phospholipase C, which is activated following ligand binding to a GPCR. This hydrolysis produces diacylglycerol and the second messenger inositol 1,4,5-triphosphate (InsP₃). Binding of the latter to its specific receptor (InsP₃R), located on the endoplasmic reticulum, triggers calcium liberation and cellular response via calmodulin and other calcium-sensitive proteins. Complex cascades of events degrade InsP3 to inositol and then recycle inositol to PIP3.

InsP $_3$ is a ubiquitous second messenger, which prompted much interest in the scientific community in the last 20 years. On the one hand, the possibility of blocking its binding to InsP $_3$ R was explored, and the search for antagonists of this receptor has been a long-standing interest. ^[7] Only a few antagonists of low potency have been found. On the other hand, InsP $_3$ R agonists, that is, analogs of InsP $_3$, have been developed to study InsP $_3$ R, the signalling pathway, or to trigger at will biologic events such as secretion, cell proliferation, or cell contraction. This task was easier, and a number of synthetic analogs of InsP $_3$ have been proposed. ^[8–10]

In our group, we studied heterocyclic structures designed by analogy with InsP₃. These sugar-based analogs of InsP₃ are potent ligands of InsP₃R. [11-15] Moreover, while our studies were in progress, adenophostins **2**, the most potent agonists of InsP₃R, have been isolated and supported our idea of replacing the cyclohexane ring of inositol by sugar templates. These molecules provide good lead compounds for the design of potent agonists. The chemistry of adenophostin and congeners has been thoroughly explored, in particular in J. van Boom group. The biologic activity of all these analogs has been explored on isolated receptor InsP₃ or on permeabilized cells and confirmed

Figure 1: Sugars based analogs of InsP₃.

the potency of these ligands to trigger calcium release from endoplasmic reticulum stores. ^[19] We were also able to construct simplified analogs of adenophostins, which we named xylophostins and which are very potent agonists of $InsP_3R$ (Fig. 1). ^[15]

As above mentioned, one interest of these agonists is their possible use as biochemical tools. Indeed, it would be of interest to trigger calcium release using the second messenger itself without external stimulus by the normal primary messenger and to trigger biologic events in intact cells. This would be particularly useful on abnormal cells not expressing GPCR.

However, the intrinsic high polarity of these water-soluble polyphosphates precludes their use on intact cells. Analogs of $InsP_3$ that could be transported across cell membranes and could undergo subsequent degradation to the free phosphate derivatives, the so-called permeant derivatives, could provide a solution to this problem. Various permeant inositol phosphates have already been proposed, $^{[20]}$ and here we report the results of our investigations along these lines using our xylose-based analogs. We also report the details of the synthetic studies and some preliminary biologic results providing the clues to cell external activation via $InsP_3$ analogs.

RESULTS AND DISCUSSION

Among the InsP₃ analogs synthesized in our group, compound **3** was found very active^[9] and would be a good candidate to test several strategies for making

this compound permeant. Different approaches were tested, and six target compounds depicted in Figure 2 were devised and prepared.

In the first series of experiments, three possibilities were explored. The simplest way was the phosphorylation of the appropriate triol with a protected alkylphosphate, assuming that the recovery of the phosphate group should be carried out via a phospholipase hydrolysis of the alkylphosphate groups. The synthesis of 5 bearing dialkylphosphate was envisioned. The chain length of the alkyl group of the dialkylphosphate should play a crucial role either in the transport or in the phosphate liberation inside the cell and would need to be carefully chosen. We chose to limit our investigation to the medium-sized octyl group. One drawback of this approach is the very low solubility in water of this type of fully protected compound. To overcome this drawback, a possibility was to decrease the number of protected phosphates Protection of each of the three phosphates with single alkyl group as in 6 was thus considered. Finally, the construction of 7 and 8, with only one of the three phosphates protected with two alkyl groups, was also envisioned. It is of note that such monoprotected trisphosphates should act as a surfactant and interact with cell membranes in several ways.

The synthesis of **5** and **6** started from the previously described triol **12** obtained in five steps from allyl- α -D-xylopyranoside via the 2-O-benzyl derivative **17**. Reaction of **12** with the phosphoramidite **15** followed by *in situ* oxidation with tBuOOH gave the protected derivative **13** in 42% yield. Hydrogenolysis of this compound gave the free hydroxyl group of **5** in good yield.

The synthesis of **6** proceeded along the same lines by changing the phosphitylating agent to **16**. The protected trisphosphate **14** was obtained in 52% yield

for the two steps. Deprotection of the four benzyl groups by hydrogenolysis at 20 bars in methanol gave the free derivative **6** isolated as the sodium salt in quantitative yield (Sch. 1).

It was known from the previous studies that the two vicinal phosphates at position 4 and 5 of the inositol ring are crucial for recognition by the InsP₃R. Thus, it could be useful to modify only the phosphate of the aglycon that mimics the phosphate at position 1 of InsP₃. The synthetic strategy toward the triol 12 allowed the construction of such unsymmetrical trisphosphates. We started from the protected allyl xyloside 17 that was phosphorylated at position 3 and 4 (carbohydrate numbering) using the phosphoramidite 23, [21] followed by oxidation with tBuOOH to give the protected bisphosphate 18 in 70% yield. The double bond was cleaved using OsO_4 and $NaIO_4$ in a dioxane-water mixture to yield the corresponding aldehyde 19 in 98% yield. Reduction of the carbonyl group with sodium borohydride in MeOH for 3 min gave the expected alcohol **20** in 57% yield. Phosphorylation of this alcohol by the phosphoramidite method using 15 gave the protected trisphosphate 21 in 42% yield after oxidation. Deprotection of the cyano-ethyl groups of 21 gave the semi-protected derivative 22. Deprotection of the cyano-ethyl groups and the benzyl group of 21 was achieved by treatment with sodium in liquid ammonia and gave quantitatively the free bisphosphate 7 (Sch. 2).

The same alcohol **20** was engaged in a phosphorylation reaction using the H-phosphonate $25^{[22]}$ in the presence of pivaloyl chloride [23] followed by oxidation with iodine in a 98:2 pyridine/water mixture [24,25] to provide the protected phosphate **24**. Removal of the cyanoethyl and benzyl groups by treatment with sodium in liquid ammonia afforded the free derivative **8** in 98% yield (Sch. 3).

Preliminary studies of the properties of the four phosphates **5–8** were rather disappointing. The biologic testings (vide infra) consisted of measuring calcium liberation from intact cells under physiologic conditions. None of

these compounds showed significant activity, which means that either these compounds do not cross the cell membrane or if they do, are not released significantly to the free phosphates. Only compound **6** showed an ionophoric effect.

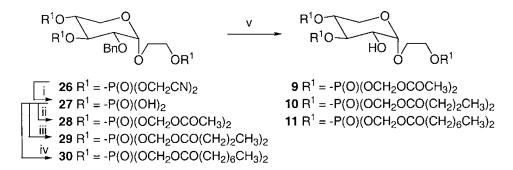

To improve the permeability and the hydrolysis to the free phosphate we turned our attention to more labile phosphate protection. [26] Acyloxy derivatives have been considered to produce prodrugs of charged or polar bioactive compounds. [27] Acetoxymethyl groups have been introduced in the phosphoinositol field to prepare permeant derivatives of InsP₃. [20,28] These groups are easily introduced on the free phosphates under smooth reaction conditions. Three different acyloxymethyl groups, octyl, butyl, and ethyl, which differed by the chain length, have been used in this study. The strategy consists of

Scheme 3: Reagents i: **BF**, pivaloyl chloride, pyridine, -20° C, 2 hr then l_2 , pyridine/ H_2 O (98/2 v:v), -20° C, then rt, 40 min; ii: Na, NH₃ liq., dioxane.

the formation of the free xylose-derived trisphosphate **27** that could be alkylated and then deprotected to give the expected permeant derivatives. Phosphorylation of **12** using the phosphoramidite **23** followed by *t*BuOOH oxidation gave the protected trisphosphate **26** in 58% yield. Removal of the phosphate groups by treatment with potassium hydroxide in methanol gave the free trisphosphate **27** in excellent yield (Sch. 4).

This key intermediate was then treated with iodomethyl octanoate prepared by a three-step sequence from octanoic acid using modification of literature procedures. The fully protected derivative **30** was obtained in modest yield. The same procedure was applied to **27** using iodomethylbutanoate prepared from the known bromoderivative and bromomethyl acetate to provide the protected derivatives **29** and **28**, respectively, in about 20% yield. Final deprotection of the 2-O-benzyl group was cleanly achieved by hydrogenolysis (20 bars H₂) in ethylacetate in the presence of palladium on charcoal as the catalyst to provide the permeant derivatives **9**, **10**, and **11**.

Given the easy access to the enantiomerically pure xylose trisphosphate **3** and given its high potency, it seemed interesting to use it to construct more complex molecular tools. Photoaffinity labelling is a key method to localize receptors in cells for example. This has been used in the inositol field and developed recently by Prestwich. ^[32] In most of these studies a photoaffinity ligand is carried by the 1-phosphate group of the inositol derivative. We have developed xylose-based analogs of InsP₃, which are equipped with an aglycon bearing the phosphate group and an anchoring point. This has been used for linking the adenine residue in the synthesis of xylophostin. We explored the same approach to construct an affinity labelling ligand of InsP₃R, in which the three phosphates would be present in a protected form to make this compound permeant. A derivative of cinnamic acid developed by Prestwich and acetoxy methyl groups were chosen as the photosensitive and protecting groups, respectively (Sch. 5).

Scheme 4: Reagents i: KOH, MeOH 0.5 M, 40° C; ii: bromomethyl acetate, DIEA, CH₃CN, rt; iii: iodomethylbutanoate, DIEA, CH₃CN, rt; iv: iodomethyl octanoate, DIEA, CH₃CN, rt; v: Pd/C 10%, H₂, 20 bars, AcOEt.

Scheme 5: Reagents i: NaH, BnBr, DMF; ii: 1) NaN₃, MeOCH₂CH₂OH, H₂O, NH₄Cl, 2) TFA/H₂O; (95/5 v:v), CH₂Cl₂; iii: Pd/C 10%, H₂, MeOH; iv: **41**, BOP, NEt₃, DMF; v: **23**, 1H-tetrazole, CH₂Cl₂, rt, then 0°C, tBuOOH; vi: KOH, MeOH 0.5 M, 40°C; vii: bromomethyl acetate, DIEA, CH₃CN, rt; viii: Pd/C 10%, H₂, 20 bars, AcOEt.

Benzylation of the 2-OH group of known epoxide **31**^[34] gave **32** in 91% yield. Treatment of this compound with sodium azide in methoxyethanol in the presence of ammonium chloride gave 33 in 80% yield. Attempts to carry out the phosphorylation steps in the presence of the azide group did not lead to the expected compounds in satisfactory yield and purity. Thus, the azide function was reduced to the corresponding amine by hydrogenolysis using 10% Pd/C in methanol for 4 hr, providing 35 in 97% yield. Coupling of the free amine with the E acid 41 in the presence of BOP reagent in DMF gave the corresponding amide 36 in 72% yield. A set of two NMR signals was observed for this compound, which is likely due to two conformational isomers in the p-benzoylcinnamyl system. Phosphitylation of the free OH groups of 36 with 23 and oxidation of the phosphites to the phosphates gave **37** in 42% overall yield. Removal of the phosphate-protecting groups in basic medium gave the free trisphosphate 38 in excellent yield. After ion exchange the diisopropylammonium salts were reacted with 10 equivalents of acetoxymethyl bromide in acetonitrile to provide the protected derivative 39 in 20% yield. All these compounds were also mixtures of conformational isomers as shown by ¹H and ¹³C NMR. The last step was removal of 2-O-benzyl group by hydrogenolysis, which was accompanied by reduction of the cinnamoyl double bond. Treatment of 39 under 15 bars of hydrogen atmosphere for $10\,\mathrm{hr}$ in the presence of 10% Pd/C in ethyl acetate was needed to achieve the benzyl group hydrogenolysis. The end product of the reaction 40 was also no longer a mixture of conformers but was also no longer a benzophenone system. Indeed, reduction of the carbonyl group occurred under such drastic hydrogenolysis conditions. This type of reduction has some literature precedents. Despite this unexpected loss of the carbonyl group, this compound has an interest as a permeant analog of $\mathrm{InsP_3}$ bearing a lipophilic group near the 1'-O-phosphate. It could be used to test a hypothesis about the potent activity of adenophostin, which should be due to lipophilic or stacking interactions between adenosine and an appropriate pocket on $\mathrm{InsP_3R.}^{[36]}$

BIOLOGICAL ACTIVITIES

The binding efficiency of the compounds $\bf 3$, $\bf 8$, and $\bf 7$ was assayed in competition binding experiments of $[^3H] Ins P_3$ to rat cerebellar membranes. The analogs inhibited specific $[^3H] Ins P_3$ binding in the following order of potency, $Ins P_3 > \bf 3 > \bf 8 > \bf 7$ (Fig. 3). This indicates that the protection of the 2'-O-phosphate with one or two alkyl groups is not detrimental to binding to the receptor, confirming the minor role of this phosphate group (corresponding to the 1-O-phosphate in $Ins P_3$) in calcium liberation. It also indicates that the phosphate esters are not cleaved under the experimental conditions to produce $\bf 3$.

Analog-evoked Ca2+ Responses in Isolated Hepatocytes

Analogs 6, 9, or 40 were added to quin2-loaded rat hepatocyte suspension and calcium responses were studied using spectrofluorimetry. All three analogs induced an increase in quin2 fluorescence, indicating an increase of the

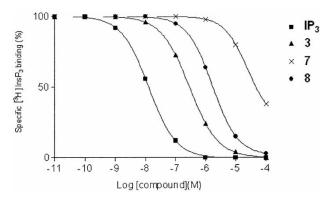

Figure 3: Inhibition of specific (3H)InsP₃ binding to rat cerebellar cells InsP₃R by 3, 7, and 8.

cytosolic Ca^{2+} concentration ($[Ca^{2+}]_c$). Maximal responses were obtained in the presence of 100 μ M of **6**, 100 μ M of **9**, and 10 μ M of **40**. In the presence of extracellular Ca^{2+} this increase of $[Ca^{2+}]_c$ is sustained, and the following addition of 10 nM of the Ca^{2+} mobilizing agonist vasopressin did not induce further ($[Ca^{2+}]_c$ increase, most likely because quin2 was saturated (Fig. 4). The $[Ca^{2+}]_c$ increase developed within 1 to 2 min after the addition of **9** or **40**. This delay is most likely due to limiting steps like the entry of the analog through the plasma membrane and to the hydrolysis of the ester function by the cell esterases. The Ca^{2+} increase developed much more rapidly after the addition of **6**; this suggests that it induced a nonspecific Ca^{2+} entry through the plasma membrane.

In the absence of extracellular Ca^{2+} , maximal concentrations of $\bf 6$ (100 μ M), $\bf 9$ (100 μ M), or $\bf 40$ (10 μ M) induced a transient $[Ca^{2+}]_c$ increase, which developed within 1 to 2 min after the addition of the analog (Fig. 5). Since there was no Ca^{2+} entry from the extracellular medium, these increases are due to the mobilization of Ca^{2+} accumulated in the intracellular Ca^{2+} store. The addition of 10 nM vasopressin evoked a calcium release through the production of $InsP_3$. This response was reduced when vasopressin was added after $\bf 6$ or suppressed when added after $\bf 9$ or $\bf 40$. This suggests that the analogs induced the release of Ca^{2+} from the same intracellular store as the one, which is sensitive to $InsP_3$, namely, the endoplasmic reticulum. Accordingly, the previous stimulation of the hepatocytes by vasopressin induced a transient increase of $[Ca^{2+}]_c$, which emptied the $InsP_3$ -sensitive Ca^{2+} store consequently, and the following addition of the analogs did not induce further Ca^{2+} release.

We have studied in more detail the effects of the analog 40 on the Ca^{2+} mobilization of quin2-loaded hepatocytes. Figure 5c indicates that the addition of $0.1\,\mu\text{M}$ of 40 to cells incubated in a Ca^{2+} -free medium did not evoke Ca^{2+} release, and the following addition of vasopressin was not precluded. The addition of $1\,\mu\text{M}$ or $10\,\mu\text{M}$ 40 induced progressive increases of

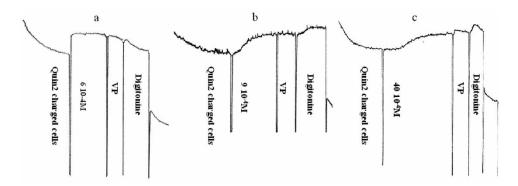

Figure 4: Calcium mobilization by **6**, **9**, and **40** in intact rat hepatocytes in the presence of extracellular calcium (1.8 nM).

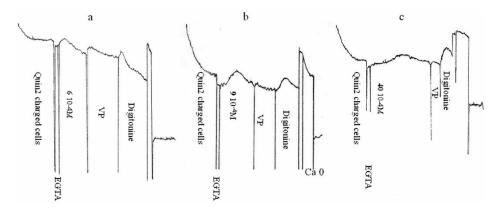

Figure 5: Calcium mobilization by 6, 9, and 40 in intact rat hepatocytes in the absence of extracellular calcium.

 $[Ca^{2+}]_c$, which led to progressive decreases of the response to vasopressin. This confirms that ${\bf 40}$ and vasopressin mobilized Ca^{2+} from the same intracellular Ca^{2+} store. The addition of $6\,\mu{\rm M}$ of thapsigargin, an inhibitor of the Ca^{2+} pump that actively accumulates Ca^{2+} in the lumen of the endoplasmic reticulum, evoked transient increases of $[Ca^{2+}]_c$ and precluded the effect of ${\bf 40}$ (Fig. 6b). This confirms that ${\bf 40}$ mobilized Ca^{2+} from the endoplasmic reticulum. Accordingly, the addition of ${\bf 40}$ before the addition of thapsigargin precluded the Ca^{2+} release by the Ca^{2+} pump inhibitor (Fig. 6a). These data clearly indicate that ${\bf 40}$ mimics the effect of $InsP_3$ in the hepatocytes.

In the presence of extracellular Ca^{2+} , increasing concentrations of **40** from $0.1\,\mu\text{M}$ to $10\,\mu\text{M}$ induced progressive increase of the $[Ca^{2+}]_c$ (Fig. 4c). This increase was maintained during the presence of the analog, and the further addition of vasopressin induced a reduced increase of $[Ca^{2+}]_c$. The sustained

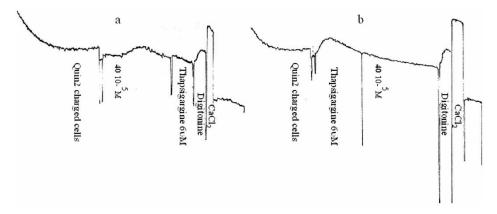

Figure 6: Effect of thapsigaraine on calcium mobilization by 40 on intact rat hepatocytes.

response observed in the presence of 40 suggests that the analog stimulated the Ca^{2+} entry through the plasma membrane. This is in agreement with the capacitative hypothesis that assumes that the stimulation of Ca^{2+} influx directly depends on the Ca^{2+} concentration in the lumen of the endoplasmic reticulum of stimulated cells. [38]

CONCLUSION

Different protected analogs of our xylose-based full agonist of $\operatorname{InsP_3} 3$ have been prepared and tested for their ability to bind the $\operatorname{InsP_3} R$ or to mobilize calcium from its internal stores. Fully protected analogs of 3 on all phosphates did not mobilize calcium in intact cells. Partially protected derivatives on 2'-O-phosphate do not cross cell membranes but bind to $\operatorname{InsP_3} R$, although less potently than 3. The most efficient compound was the acetoxymethyl derivative 9, which crossed cell membranes and is able to mobilize calcium, other acyloxy derivatives being less interesting. Interestingly, compound 40, primarily designed as a photoaffinity ligand, is also a good permeant agonist of $\operatorname{InsP_3} R$. This should be in favor of the existence of a hydrophobic pocket on the receptor that can accommodate a rather large aromatic group like adenosine or the phenyl benzyl group of 40. All these analogs can serve as biologic tools for further investigation of the calcium-signalling pathway.

EXPERIMENTAL SECTION

Optical rotations were determined at 20°C with a Perkin Elmer model 141 automatic polarimeter. NMR spectra were recorded at 25°C with a Bruker AC250 spectrometer. Chemical shift (δ) are given in ppm relative to the signal for internal tetrametylsilane for ^{1}H NMR and indirectly to the central line of CDCl₃, δ 77.03 for ^{13}C NMR spectra; those in deuterium oxide are reported relative to external 2,3 dimethyl-2-silapentane-5 sulfate (DSS). Infrared spectra were recorded on a Perkin-Elmer Spectrum 1000 FTIR spectrometer. All reactions were monitored by thin layer chromatography on Kieselgel $60F_{254}$ (Merck) with detection by UV light and/or by charring with 15% sulfuric acid in ethanol. Elemental analyses and mass spectra were performed by the Service Central d'Analyses du CNRS at Vernaison (France).

General procedure for ozonolysis followed by a reductive cleavage (**Procedure A**): A solution of allyl xyloside (1 mmol) in a dichloromethane-methanol mixture (10 mL, 1:1 v/v) was cooled to -70°C and ozone was bubbled through the solution (flow of 0.4 L/min) until the disappearance of the starting material. The solution was degassed using a stream of argon for 15 min. Sodium borohydride (4 eq.) was added and the reaction mixture was allowed to warm to rt. After completion of the reaction (TLC monitoring) the

solvents were evaporated under reduced pressure and the residue was diluted with ethyl acetate. The organic layer was washed with 3N hydrochloric acid and water, dried over magnesium sulfate, and concentrated to provide the corresponding 2-hydroxyethyl derivative.

General procedure for phosphorylation reactions (Procedure B): To a solution of the alcohol derivative in dichloromethane ($12\,\mathrm{mL/mmol}$) were added under argon 1H-tetrazole ($4\,\mathrm{eq./OH}$) and the required phosphoramidite ($2.5\,\mathrm{eq./OH}$). The reaction mixture was stirred at rt until TLC and $^{31}\mathrm{P}$ NMR spectroscopy analysis showed complete conversion of starting material into the corresponding phosphite derivative. The solution was cooled to $0^{\circ}\mathrm{C}$, an excess of $t\mathrm{BuOOH}$ was added, and the reaction mixture was warmed to rt. After completion of the reaction (TLC monitoring), the medium was diluted with dichloromethane; successively washed with water, saturated aqueous NaHCO₃ solution, and water; dried over magnesium sulfate; and concentrated in vacuo. The residue was purified by column chromatography.

General procedure for hydrogenolysis reactions (Procedure C): To a mixture of the phosphorylated derivative in methanol (40 mL/mmol) was added the same amount of 10% Pd/C. The mixture was placed under hydrogen atmosphere at 20 bars. After 14 hr, the catalyst was removed by filtration on a pad of Celite and the solvent evaporated in vacuo. In the case of the presence of benzylic phosphodiester groups, the residue was dissolved in water and aqueous NH₃ was added to reach pH 8.0, and the solution was applied to a column of Bio-Rad Chelex 100 resin (Na⁺ form). The compound was eluted with water; fractions containing the desired compound were combined and freeze dried.

General procedure for debenzylation using sodium in liquid ammonia (Procedure D): Liquid ammonia was condensed into a two-necked flask at -78° C and sodium was added. A solution of a benzylated compound in dry dioxane was added and the mixture was stirred for 20 min. The reaction was quenched with ethanol and the medium was warmed to rt. The solution was degassed with nitrogen for 15 min, neutralized to pH 7.00 with DOWEX 50W (H⁺) cation exchange resin, and filtered, and the resin was washed with deionized water. After evaporation of the solvents, the residue was applied to a column of Bio-Rad Chelex 100 resin (Na⁺ form). The compounds were eluted with water; fractions containing the desired compound were combined and freeze dried.

General procedure for methanolic cleavage of cyanoethyl phosphate (**Procedure E**): The protected compound was dissolved in a 0.5M potassium hydroxide methanolic solution (2.3 OH equivalent/phosphate group). The solution was heated at 35°C until all the cyanoethyl groups were removed (³¹P NMR monitoring) and then allowed to cool to rt. The solution was neutralized to pH 7.00 with DOWEX 50W (H⁺) cation exchange resin and filtered, and

the resin was washed with deionized water. After evaporation of the solvents the residue was applied to a column of Bio-Rad Chelex 100 resin (Na⁺ form). The column was eluted with water; fractions containing the desired compound were combined and freeze dried.

(2-Hydroxyethyl) 2-*O*-benzyl-α-D-xylopyranoside (12). The allyl xyloside 17 (2.22 g, 7.92 mmol) was converted into 2-hydroxyethyl derivative according to procedure A to provide 12 (1.84 g, 6.5 mmol, 82%) as a syrup. R_f 0.65 (CH₂Cl₂/MeOH,9:1); [α]_D + 65.0 (c 2.8, CHCl₃); IR 3374 (OH) cm⁻¹; ¹H NMR (CDCl₃) δ 7.23–7.36 (m, 5H, Ar); 4.66 (AB, 1H, J_{AB} 11.5 Hz, CH₂Ph); 4.56 (d, 1H, J₁₋₂ 3.5 Hz, *H*-1); 4.52 (AB, 1H, CH₂Ph); 4.49 (m, 1H, O*H*); 4.28 (m, 2H, O*H*); 3.83 (dd, 1H, J₂₋₃ 9.6, J₃₋₄ 8.5 Hz, *H*-3); 3.56–3.68 (m, 3H, *H*-1'a, *H*-1'b, *H*-5ax); 3.44–3.49 (m, 1H, *H*-2'a); 3.38–3.42 (m, 1H, *H*-2'b); 3.33–3.37 (m, 1H, *H*-4); 3.29 (dd, 1H, J_{4-5eq} 4.5, J_{5eq-5ax} 11.5 Hz, *H*-5eq); 3.23 (dd, 1H, *H*-2); ¹³C NMR (CDCl₃) δ 137.8 (*C* ipso); 128.3; 127.9; 127.8; (5C, *C* Ar); 96.7 (*C*-1); 79.5 (*C*-3); 72.9 (*C*-2); 73.4 (*C*H₂Ph); 69.9 (*C*-4); 69.5 (*C*-1'); 61.3 (2C, *C*-5, *C*-2'). Octyl phosphonate triethylamonium salt (25). To a solution of 1-octanol (651 mg, 5 mmol) and NEt₃ (1.39 mL, 10 mmol) in dioxane (7 mL) was added under argon a dioxane solution (5 mL) of 2-chloro-1,3,2-benzodioxaphosphorin-4-one (1.01 g, 5 mmol). After 30 min at rt, 31 P NMR indicated complete consumption of the starting chlorophosphite (149.6 ppm) to give a product with a signal at 125.6 ppm; water (1 mL) was then added to the medium. The solvents were evaporated to dryness and the residue was coevaporated twice with toluene. Compound **25** (812 mg, 2.73 mmol) was as a white solid in 55% yield after purification by column chromatography (AcOEt \rightarrow AcOEt/MeOH

85:15). $^{1}{\rm H}$ NMR (250 MHz, CDCl₃): δ 6.78 (d, 1H, J_{P-H} 628 Hz, P-H); 3.85 (m, 2H, 2H-1); 3.03 (q, 6H, J 7.1 Hz, N(CH₂CH₃)₃); 1.53–1.67 (m, 2H, 2H-2); 1.13–1.40 (m, 19H, 2(H-3, H-3', H-4, H-4', H-5, H-5', H-6, H-6', H-7, H-7'), N(CH₂CH₃)₃)); 0.83 (t, 3H, J_{H-H} 5.8 Hz, 3H-8). $^{13}{\rm C}$ NMR (CDCl₃): δ 63.8 (d, $^{2}{\rm J_{C-P}}$ 409 Hz, C-1); 4504 (s, 3C, N(CH₂CH₃)₃; 3104 (s, C-6); 3003 (d, $^{3}{\rm J_{C-P}}$ 703 Hz, C-2); 2808 (s, 2C, C-4, C-5); 25.4 (s, C-3); 22.2 (s, C-7); 13.8 (s, C-8); 8.2 (s, 3C, N(CH₂CH₃)₃); $^{31}{\rm P}$ NMR (CDCl₃): δ 3.51 (s, 1P).

[(2-Octylphosphonoxy)ethyl] 2-O-benzyl-3,4-bis[(2-cyanoethyl)phosphate] α-D-xylopyranoside (24). To a solution of xyloside 20 (250 mg, 0.37 mmol) and H-phosphonate monoester 25 (1 eq., 110 mg, 0.37 mmol) in pyridine (5 mL) was added dropwise a solution of pivaloyl chloride (3 eq., 0.13 mL, 1.11 mmol) in pyridine (1 mL) at -20° C for 25 min under argon. After being stirred for 2 hr, a solution of iodine (1.25 eq., 118 mg, 0.46 mmol) in a pyridine/water mixture (0.9 mL, 98:2, v/v) was added. The medium was warmed to rt and after 45 min, a solution of sodium sulfite in water (1%) was added until complete discoloration of the medium. The solvents were evaporated in vacuo, the residue was coevaporated three times with toluene and the crude product was purified by column chromatography on silicic acid (EtOAc/ MeOH $98:2 \rightarrow 80:20$) and then on LH20 Sephadex gel (CHCl₃/MeOH 1:1) to give **24** (40%, 140 mg, 0.15 mmol) as a gum. $[\alpha]_D + 23.0$ (c 0.98, CHCl₃); IR 2251 (CN); 1280 (P=O); 1038 (P-O) cm⁻¹; ¹H NMR (250 MHz, CDCl₃/MeOD, 1:1) δ $7.07 - 7.29 \text{ (m, 5H, } H \text{ Ar); } 4.73 \text{ (d, 1H, } J_{1-2} 2.9 \text{ Hz, } H-1); } 4.37 - 4.60 \text{ (m, 3H, } H-3)$ CH_2Ph); 3.47–4.34 (m, 17H, H-4, H-5, H-5', H-1'a, H-1'b, H-2'a, H-2'b, 2H-1", 4CH₂CH₂CN); 3.41 (dd, 1H, J₂₋₃ 9.5 Hz, H-2); 3.14 (q, 6H, J 7.1 Hz, 2.50-2.75 (m, 6H, $3CH_2CH_2CN$); 2.17-2.49 (m, $N(CH_2CH_3)_3$; CH_2CH_2CN ; 1.32–1.61 (m, 2H, 2H-2"); 0.85–1.30 (m, 19H, 2(H-3"a, H-3"b, H-4''a, H-4''b, H-5''a, H-5''b, H-6''a, H-6''b, H-7''a, H-7''b), $N(CH_2CH_3)_3$); 0.56-0.77 (t, 3H, J_{H-H} 5.8 Hz, 3H-8"); 13 CNMR(CDCl₃/MeOD, 1:1) δ 136.8 (Cipso); 128.0; 127.9; 127.6 (5C, CH Ar); 117.6 (s, CN); 95.8 (C-1); 77.9 (m, C-3); 77.1 (C-2); 74.1 (m, C-4); 72.1 (CH₂Ph); 67.2 (m, C-1'); 62.2-63.3 $(m, 6C, C-1'', C-2', 4CH_2CH_2CN); 58.6 (C-5); 45.8 (s, 3C, N(CH_2CH_3)_3); 31.4$ (C-6"); 30.0 (d, ³J_{C-P} 7.2 Hz, C-2"); 29.2; 28.9 (2C, C-4", C-5"); 25.4 (C-3"); 22.2 (C-7''); 13.4 (C-8''); 8.0 (3C, N(CH₂CH₃)₃); ³¹PNMR (CDCl₃/MeOD, 1:1) δ -2.43; -1.78 (2s, $2OPO(OCH_2CH_2CN)_2$); 0.40 (s, $OPORO_2^-$); ESI-MS (negative mode): Calcd for $C_{34}H_{51}O_{15}N_4P_3 \ m/z$: 847 [M-H]⁻.

Anal. Calcd for $C_{32}H_{41}O_{15}N_6P_3$: C, 45.61; H, 4.90; N, 9.97; P, 11.03. Found: C, 45.37; H, 4.85; N, 10.15; P, 10.92.

[2-(Phosphonoxy)ethyl] 2-*O*-benzyl-3,4-bis(dihydrogen-phosphate) α-D-xylopyranoside hexasodium salt (27). Compound 27 was obtained as a white solid by treatment of 26 according to procedure E. [α]_D + 26.0 (c 1.5, H₂O); IR 1232 (P=O), 1100 (P-O) cm⁻¹. ¹H NMR (250 MHz D₂O): δ 7.37–7.62 (m, 5H, *H* Ar); 4.95 (AB, 1H, J_{AB} 11.9 Hz, C*H*₂Ph); 4.70–4.87 (m, 2H, *H*-1, C*H*₂Ph); 4.46 (ddd, 1H, J₂₋₃ 9.2, J₃₋₄ 9.0, ³J_{H-P} 7.9 Hz, *H*-3); 4.09 (dddd, 1H, *H*-4); 3.90–4.02 (m, 2H, *H*-2'a, *H*-2'b); 3.74–3.89 (m, 2H, *H*-5eq, *H*-1'a); 3.57–3.73 (m, 3H, *H*-2, *H*-5ax, *H*-1'b); ¹³C NMR (D₂O): δ 138.2 (s, C_{ipso}); 129.4; 129.0 (2s, 5C, CH Ar); 99.4 (s, C-1); 79.9 (d, ³J_{C-P} 3.8 Hz, C-2); 79.1 (dd, ²J_{C-P} 5.9, ³J_{C-P} 4.7 Hz, C-3); 76.0 (s, CH₂Ph); 74.5 (dd, ²J_{C-P} 4.8 Hz, C-4); 70.0 (d, ³J_{C-P} 7.6 Hz, C-1'); 65.9 (d, ²J_{C-P} 4.8 Hz, C-2'); 59.1 (s, C-5). ³¹P NMR (D₂O): δ 7.66; 6.84 (2s, 20*P*O₃²⁻); 4.25 (s, C-2'O*P*); ESI-MS (Negative mode): Calcd for C₁₄H₂₃O₁₅P₃ m/z: 611 [M-5H + 4Na]⁻; 589 [M-4H + 3Na]⁻; 567 [M-3H + 2Na]⁻; 545 [M-2H + Na]⁻; 523 [M-H]⁻.

[(2-(Diacetoxymethylphosphonoxy)ethyl] 2-O-benzyl-3,4 bis(diacethoxymethyl)phosphate α-D-xylopyranoside (28). Compound 27 (139 mg,

0.21 mmol) was dissolved in water (2 mL) and applied to column of DOWEX 50W H⁺ resin. The column was eluted with deionized water; fractions containing the free phosphate compound (114 mg, 0.21 mmol) were combined and freeze dried. The resulting powder was suspended in acetonitrile (1.45 mL) containing N,N-diisopropylethylamine (0.3 mL). The suspension was sonicated and concentrated. This operation was repeated twice or more to get an oily residue, which was dissolved in acetonitrile (1.45 mL), and then DIEA (0.73 mL) and acetoxymethyl bromide (1.95 g, 12.78 mmol) were added. The solution was stirred 28 hr (³¹P RMN monitoring) at rt and the solvent was concentrated. Compound 28 (80 mg, 0.08 mmol, 39%) was obtained as a gum after purification by column chromatography (AcOEt). R_f 0.24 (AcOEt/MeOH, 98: 2); $[\alpha]_D + 22.8$ (c 0.7, CHCl₃); IR: 1766 (C=O); 1216 (P=O) cm⁻¹; ¹H NMR (250 MHz CDCl_3) : $\delta 7.21-7.39 \text{ (m, 5H, } H \text{ Ar)}$; $5.42-5.73 \text{ (m, 12H, 6O-C}H_2-O)$; 4.62-4.78 (m, 3H, H-1, H-3, CH_2Ph); 4.55 (AB, 1H, J_{AB} 11.7 Hz, CH_2Ph); 4.37 (dddd, 1H, H-4); 4.18-4.30 (m, 2H, H-2'a, H-2'b); 3.88 (ddd, 1H, J_{4-5eq} 5.8, $J_{5eq-5ax}$ 11. ${}^{4}J_{H-P}$ 2,9 Hz, H-5eq); 3.76 (dddd, 1H, H-1'a); 3.51–3.70 (m, 1H, H-5ax, H-1'b); 3.44 (dd, 1H, J₁₋₂ 3.6, J₂₋₃ 9.5 Hz, H-2); 2.12; 2.10; 2.07 (3s, 18H, 6C H_3 C=O); ¹³C NMR (CDCl₃): δ 168.9 (s, 6C, 6C=O); 137.1 (s, C_{ipso}); 128.2; 127.8 (2s, 5C, CH Ar); 96.4 (s, C-1); 81.5–82.5 (6d, 6C, 6OCH₂C=O); 77.7 (dd, ²J_{C-P} 7.3 Hz, C-3); 77.0 (s, C-2); 73.6 (dd, ²J_{C-P} 4.9 Hz, C-4); 72.8 (s, CH₂Ph); 66.5 (m, 2C, C-1', C-2'); 58.7 (s, C-5); 20.3 (s, 6C, $6CH_{3}C\!\!=\!\!O); \ ^{31}P \ NMR \ (CDCl_{3}; \ 100\,MHz); \ \delta \ -2.98; \ -3.31 \ (2s); \ -3.95$ (s, C-2'OP). ESI-MS (positive mode): Calcd for $C_{32}H_{47}O_{27}P_3 \ m/z$: 956 [M]⁺.

[(2-(Dibutyryloxymethylphosphonoxy)ethyl] 2-O-benzyl-3,4 bis(dibutyryloxymethyl phosphate) α -D-xylopyranoside (29). Compound 29 was obtained as a gum in 22% yield after purification by column chromatography $(AcOEt/Hex 65:35 \rightarrow 75:25)$ by treatment of **27** with butyryloxymethyl iodide using the procedure described for the preparation of 28. R_f 0.3 (Hex/AcOEt, 3:7), $[\alpha]_D + 20.0$ (c 0.6, CHCl₃); IR 1766 (C=O); 1218 (P=O) cm⁻¹; ¹H NMR $(250 \,\mathrm{MHz} \,\mathrm{CDCl_3}): \delta 7.22 - 7.42 \,\mathrm{(m, 5H, } H \,\mathrm{aromatics}); 5.46 - 5.77 \,\mathrm{(m, 12H, } L)$ 6O-CH₂-O); 4.65-4.82 (m, 3H, H-1, H-3, CH₂Ph); 4.55 (AB, 1H, J_{AB} 11.7 Hz, CH₂Ph); 4.36 (dddd, 1H, H-4); 4.17–4.32 (m, 2H, H-2'a, H-2'b); 3.89 (ddd, 1H, J_{4-5eq} 5.8, $J_{5eq-5ax}$ 11. ${}^{4}J_{H-P}$ 2.9 Hz, H-5eq); 3.77 (dddd, 1H, H-1'a); 3.50–3.69 (m, 2H, H-5ax, H-1'b); 3.44 (dd, 1H, J_{1-2} 2.9, J_{2-3} 9.5 Hz, H-2); 2.23–2.43 (m, 12H, 6H-1"a, 6H-1"b); 1.56-1.75 (m, 12H, 6H-2"a, 6H-2"b); 0.88-1.04 (m, 18H, 6C H_3); ¹³C NMR (CDCl₃): δ 171.5 (s, 6C, 6C=O); 137.1 (s, C_{ipso}); 128.2; 127.8 (2s, 5C, CH Ar); 96.4 (s, C-1); 82.0-82.8 (6d, 6C, 6OCH₂C=O); 77.7 (dd, ²J_{C-P} 6.1, ³J_{C-P} 7.3 Hz, *C*-3); 77.0 (s, *C*-2); 73.6 (dd, J_{C-P} 4.8 Hz, *C*-4); 72.7 (s, CH₂Ph); 66.4 (2d, 2C, C-1', C-2'); 58.7 (s, C-5); 35.3 (s, 6C, 6C-1"); 17.6 (s, 6C, 6C-2"); 13.2 (s, 6C, 6CH₃); 31 P NMR (CDCl₃; 100 MHz): $\delta - 3.07$; - 3.37(2s); -3.99 (s, C-2'OP); Anal. [3-(p-Benzoylcinnamido)-2(S)-hydroxy-propyl] 2-O-benzyl- α -D-xylopyranoside (36). To a solution of 41 (257 mg, 1 mmol) in DMF (3 mL) were added NEt₃ (0.15 mL, 1.12 mmol) and BOP (495 mg, 1.12 mmol). The mixture was stirred at rt for 15 min and then a solution of 35 (319 mg, 1 mmol) in DMF (7 mL) was added. After 40 min, the solvent was removed in vacuo and the residue was diluted with ethyl acetate. The organic layer was washed with 3N HCl and water, dried over Na₂SO₄, and concentrated. Compound 36

(398 mg, 0.73 mmol) was obtained as a gum in 72% yield after purification by column chromatography (CH₂Cl₂/MeOH 97:3 \rightarrow 94:6). R_f 0.50 (CH₂Cl₂/MeOH 9:1); [α]_D + 33.4 (c 1.0, CHCl₃); IR 3351 (OH, NH); 1658; 1651; 1645 (PhC(O)Ph-, OC(O)N, -Ph-C=C-) cm⁻¹; ¹H NMR (250 MHz CDCl₃): δ 7.65–7.78 (m, 2H, H Ar); 7.39–7.63 (m, 8H, -C=CHPh, H Ar); 7.19–7.35 (m, 5H, H Ar); 7.11 (t, 1H, J, NH); 6.56 (d, 1H, J_{trans} 15.4 Hz, -C=CHC(O)); 4.48–4.77 (m, 3H, CH₂Ph, H-1); 3.82–4.00 (m, 3H, H-3, H-2', OH); 3.23–3.70 (m, 8H, H-4, H-5a, H-5b, H-2, H-1'a, H-1'b, H-3'a, H-3'b); 2.93 (s, 2H, OH); ¹³C NMR (CDCl₃): 196.1 (C=O); 166.6 (C(O)NH); 139.3 (C=C-Ph); 138.3; 137.7; 137.1; 136.8 (4s, 4C, C_{ipso}); 132.7; 130.2; 129.6; 128.3; 128.0; 127.3 (6s, 14C, CH Ar); 122.8 (C=C-C(O)); 96.8 (s, C-1); 79.4 (s, C-2); 73.3 (s, CH₂Ph); 72.8 (s, C-3 or C-2'); 69.9 (s, C-3 or C-2'); 69.8 (s, C-1'); 68.9 (s, C-4); 61.3 (s, C-5); 42.7 (s, C-3'); Anal. [3-Biphenyldihydrocinnamido)2(S) (diacetoxymethylphosphonoxy) propyl] 3,4-bis(diacetoxymethyl)phosphate α -D-xylopyranoside (40). Compound 40 was quantitatively obtained as a gum by treatment of 39 using the procedure described for the preparation of **9.** $[\alpha]_D + 27.0$ (c 0.5, $CHCl_3$; IR 3315 (NH); 1768 (OC(O)CH₃); 1668 (OC(O)N); 1216(P=O); 1151(P-O) cm⁻¹; ¹H NMR (250 MHz CDCl₃): δ 7.23–7.33 (m, 2H, H Ar); 7.12-7.21 (m, 7H, H Ar); 6.48 (t, 1H, $J_{NH-H3'a} = J_{NH-H3'b}$ 5.9 Hz, NH); 5.50-5.76 (m, 12H, O-C H_2 -O); 4.81 (d, 1H, J_{1-2} 3.6 Hz, H-1); 4.53–4.68 (m, 2H, H-3, H-2'); 4.37 (m, 1H, H-4); 3.87-3.99 (m, 3H, H-5a, Ph-CH₂-Ph-); 3.74 (dd, 1H, $J_{1'a-1'b'}$ 11.0, $J_{1'a-2'}$ 6.6 Hz, H-1'a); 3.40–3.68 (m, 5H, H-2, H-5b, H-1'b, H-3'a, H-3'b); 2.91 (m, 2H, CH_2 Ph-); 2.51 (m, 2H, CH_2 C(O)); ¹³C NMR $(CDCl_3)$: δ 172.6 (C(O)NH); 169.1; 168.9 $(2s, 6C, 6OC = OCH_3)$; 140.8; 138.8; 138.1 (3s, 3C, $C_{\rm ipso}$); 128.7; 128.5; 128.1 (3s, 5C, CH Ar); 98.5 (s, C-1); 81.6– 82.8 (6d, 6C, 6OCH₂C=O); 79.6 (dd, ²J_{C-P} 5.2, ³J_{C-P} 7.1 Hz, C-3); 77.0 (m, 1C, C-2'); 73.4 (dd, ${}^{2}J_{C-P}$ 4.8, ${}^{3}J_{C-P}$ 5.2 Hz, C-4); 70.7 (s, C-2); 67.1 (d, ${}^{3}J_{C-P}$ 4.3 Hz, C-1'); 59.1 (s, C-5); 41.2 (s, -PhCH₂Ph); 39.9 (m, C-3'); 37.6 (s, CH₂C(O)); 30.7

(s, CH_2Ph -); 20.3 (s, 6C, 6 CH_3C =O); ³¹P NMR (CDCl₃; 100 MHz): δ -3.36; -3.83; -3.91 (3s, 3P); Anal. Calcd for $C_{42}H_{58}N_1O_{28}P_3$: C, 45.13; H, 5.23; N, 1.25; P, 8.31. Found: C, 45.31; H, 5.11; N, 1.07; P, 8.19.

Biological Evaluation

The preparation of rat cerebellar microsomes was achieved according to ref. 15.

Rat hepatocytes were isolated by the two-step collagenase perfusion technique, ^[39] modified as described in ref. 40. Cell viability, as assessed by trypan blue exclusion, was >96%. After isolation, cells were maintained in suspension in Eagle's medium supplemented with $15\,\mathrm{g/L}$ gelatin and gassed with O2/CO2 (19:1) at rt, during the following 8 hr, during which $[Ca^{2+}]c$ determination was performed.

Equilibrium [³H]InsP₃-binding studies were achieved according to the procedure described in ref 15.

Spectrofluorimetry studies: Before experiment, cells were loaded with the Ca²⁺-sensitive indicator quin2-acetoxymethyl (AM) ester. Briefly, an aliquot corresponding to 10^6 cells was incubated at $37^{\circ}\mathrm{C}$ in $0.5\,\mathrm{mL}$ incubation medium containing $50\,\mu\mathrm{M}$ quin2-AM for 180 seconds, centrifuged, washed, and resuspended in $2\,\mathrm{mL}$ of Dulbecco's modified Eagle medium. The cell suspension was then transferred to the oxygenated spectrofluorimeter cuvette (under $02/\mathrm{CO2}$ (19:1)) and stirred magnetically at $37^{\circ}\mathrm{C}$ (JY3D fluorometer, Jobin & Yvon). Calcium movements were measured from the observed changes in the fluorescence of quin2 (excitation wavelength, $340\,\mathrm{nm}$; emission wavelength, $492\,\mathrm{nm}$). At the end of each experiment, the fluorescence signal was calibrated by making the cell membrane permeable with $5\,\mu\mathrm{g}/\mathrm{mL}$ digitonin (quin2 saturation by external Ca²⁺ gave maximal fluorescence) and then by adding $20\,\mathrm{mM}$ EGTA to the suspension of lyzed cells to obtain the minimal fluorescence.

Experiments in Ca²⁺-free medium were performed to evaluate the mobilization of intracellular Ca²⁺ during hormone or analog stimulation. The Ca²⁺ influx was suppressed by adding EGTA (4 mM) to the incubation medium. The hormone or analogs were then added to the medium before the addition of the hormone or analog.
