### Abstract

Four novel ON donor Schiff bases (E)-2-((4-phenoxyphenylimino)methyl)phenol (HL<sub>1</sub>), (E)-2-((4-(4-biphenyloxy)phenylimino)methyl)phenol(HL<sub>2</sub>), (E)-2-((4-(naphthalen-1-yloxy)phenylimino)methyl)phenol(HL<sub>3</sub>) and (E)-2-((4-(2-naphthoxy)phenylimino)methyl)phenol (HL<sub>4</sub>) have been synthesized and characterized by various spectroscopic, analytical and electro-analytical techniques. Single crystal X-ray diffraction analysis of Schiff base (HL<sub>3</sub>) revealed that phenol and anthracene rings are inclined at 30.25(9)° and 89.64(4)° to the central phenyl ring, respectively. Intra and inter molecular interactions are observed in single crystal analysis of HL<sub>3</sub>. Intramolecular interactions are hydrogen bonding but most of the intermolecular interactions are of the C-H...π type. There is a bit of π...π stacking between the anthracene groups. Only compounds (HL<sub>1</sub>) and (HL<sub>3</sub>) have been investigated for the biological activities due to slight solubility of (HL<sub>2</sub>) and (HL<sub>4</sub>) in DMSO. The results of brine shrimp cytotoxicity assay indicated LD<sub>50</sub> values <1 μg/ml showing significant antitumor activity with IC<sub>50</sub> values 14.20 and 4.54 μg/ml respectively. The compounds were highly active in protecting DNA against hydroxyl free radicals in concentration dependent manner. Voltammetric results indicated the one electron irreversible oxidation product is formed due to hydroxyl moiety and the process is diffusion controlled. On exposing to DNA environment the electrooxidised product developed electrostatic linkage and groove binding intercalation while consuming the DNA concentration substantially. The binding strength was quantitative in terms of drug-DNA binding of the order of 10<sup>4</sup> M<sup>-1</sup>.

**Keywords:** Schiff bases, electrochemical studies, pharmacological studies, DNA-interaction

## 43 1. Introduction

44  
45 Schiff bases are most widely used organic compounds that coordinate to metal ions via  
46 azomethine nitrogen and have a wide variety of applications in many fields including analytical,  
47 biological, and inorganic chemistry. In azomethine derivatives, the C=N linkage is present in  
48 various natural (ancistrocladidine have antimalarial activity), natural-derived (chitosin-derived  
49 Schiff bases have antifungal activity), and non-natural compounds which is essential for  
50 biological activity[1]. Several azomethines possess remarkable antibacterial, antifungal,  
51 anticancer and diuretic activities. The nitrogen atom of azomethine may be involved in the  
52 formation of a hydrogen bond with the active centers of cell constituents and interferes in normal  
53 cell processes[2]. Apart from biological activities, they have found applications in many other  
54 fields such as intermediates in organic synthesis, dyes, pigments, polymer stabilizers, corrosion  
55 inhibitors, fungicidal, agrochemical, analytical chemistry, electrical conductivity, magnetism,  
56 host guest chemistry, ion exchange, nonlinear optics and catalysis [3-10]. Schiff bases have  
57 played an important role in the development of coordination chemistry and inorganic  
58 biochemistry as well. They have been used for the synthesis of a number of biologically and  
59 industrially active compounds like formazans, 4-thiazolidinines, benzoxazines, and so forth, via  
60 ring closure, cycloaddition and replacement reactions [11].

61 Particularly salicylaldehyde-Schiff bases derived from salicylaldehyde and primary amines have  
62 recently acquired a considerable importance due to their promising biological properties. Such  
63 Schiff bases are found to be a versatile pharmacophore for design and development of various  
64 bioactive lead compounds. These Schiff bases may act as bidentate-O, N and a tridentate -O, O,  
65 N donor ligand etc[12]. which can be employed for the synthesis of various coordination  
66 complexes. Cambridge structural database have shown that about 42% of Schiff bases  
67 synthesized worldwide are derived from salicylaldehyde based aldehydes and almost 68% of  
68 Schiff base complexes are synthesized from such ligands [13]. A very useful application of such  
69 new compounds is that they specially target DNA molecule with significant potential and thus  
70 can be proposed as drugs. Among other techniques the voltammetric methods have established a  
71 prominent role to study drug-DNA interaction due to high sensitivity, selectivity, versatility and  
72 fast detection ability in addition to cost effectiveness. Monitoring of the reaction of interest at the  
73 electrode surface helps to elucidate the mechanism of drug- DNA interactions [14-16].

74 In the present work (E)-2-((4-phenoxyphenylimino)methyl)phenol (HL<sub>1</sub>), (E)-2-((4-(4-  
75 biphenyloxy)phenylimino)methyl)phenol (HL<sub>2</sub>), (E)-2-((4-(naphthalen-1-yloxy)phenylimino)  
76 methyl)phenol (HL<sub>3</sub>) and (E)-2-((4-(2-naphthoxy)phenylimino)methyl)phenol (HL<sub>4</sub>) were  
77 synthesised and characterized successfully by various spectroscopic, analytical, advanced  
78 electro-analytical techniques and single crystal analysis. As Schiff bases are biological active in  
79 nature therefore synthesised compounds (HL<sub>1</sub>-HL<sub>4</sub>) were studied to acquire valuable information  
80 about their role in cellular vicinities. Biological studies (cytotoxic, antitumor and inhibition of  
81 hydroxyl (OH) free radical induced DNA damage assay) were proceeded to screen the  
82 pharmacological importance of the compounds. Voltammetric studies were carried to investigate  
83 the redox behaviour and to identify the electrophoric centres in the compounds. Further, the  
84 interactions with the DNA and the binding mode of the synthesised compounds were also  
85 investigated.

## 86 87 2. Experimental

88

## 89 2.1. Materials and methods

90

91 Solvents used were purified by standard distillation procedure and drying methods [17]. The  
92 Schiff bases (HL<sub>1</sub> –HL<sub>4</sub>) were prepared by condensation reactions of salicylaldehyde and  
93 corresponding aromatic amines [18] already reported by our research group in ethanol following  
94 the reported method [19-20]. The progress as well as purity of products was checked by thin layer  
95 chromatography on pre-coated Kieselgel 60HF TLC plates. Elemental analysis was carried out  
96 on a CHNS 932 (Leco-USA) elemental analyzer. Melting points were determined, using a MPD  
97 Mitamura Riken Kogyo (Japan) electrothermal melting point apparatus. FTIR spectra were  
98 recorded on a Thermoscientific (USA) Nicolet 6700 spectrometer in the frequency range of  
99 4000-400 cm<sup>-1</sup>. <sup>1</sup>H NMR (300MHz) and <sup>13</sup>C NMR (75MHz) spectra were recorded on a Bruker  
100 NMR Spectrometer.

101 Single crystal of Schiff base (HL<sub>3</sub>) was obtained by the slow evaporation of ethanol from the  
102 mother liquor at room temperature. X-ray data were collected at 150(2) K on a Bruker Apex II  
103 CCD diffractometer using MoK<sub>α</sub> radiation ( $\lambda = 0.71073\text{\AA}$ ). The structure was solved by direct  
104 methods [21] and refined on F<sup>2</sup> using all the reflections [22]. All the non-hydrogen atoms were  
105 refined using anisotropic atomic displacement parameters and hydrogen atoms bonded to carbon  
106 were inserted at calculated positions using a riding model. The phenolic proton was located and  
107 its coordinates refined. Parameters for data collection and refinement are summarised in Table 1.

108 The bioactive nature of the synthesized compounds was evaluated by brine shrimp lethality  
109 assay [23]. Brine shrimp (*Artemiasalina*) eggs (Ocean Star Inc., USA) were hatched in shallow  
110 rectangular dish (22×32 cm) filled with prepared seawater (34 g/l) under constant aeration for 48  
111 h at room temperature. After 24 h, phototropic nauplii (brine shrimp larvae) were shifted to glass  
112 vial by Pasteur pipette and 25  $\mu$ l of the each stock solution (0.1  $\mu$ g/ml, 1  $\mu$ g/ml, and 10  $\mu$ g/ml) of  
113 the test compound was added. The volume of test compounds from their stock solutions was  
114 raised up to 5 ml of artificial seawater with 10, 1, 0.5, 0.25, 0.125 and 0.0625  $\mu$ gml<sup>-1</sup> final  
115 concentration. Three replicates were prepared for each concentration. The vials were maintained  
116 under illumination at room temperature. After 24 h of incubation survivors were observed and  
117 LD<sub>50</sub> (Lethal Dose that killed 50% of shrimps) was calculated by using Finny (1971) software  
118 [24].

119 Antitumor activity of the synthesized compounds was checked by executing modified potato disc  
120 antitumor assay [25]. Inoculum with three different concentrations (1000, 100 and 10  $\mu$ g/ml) was  
121 prepared containing 48 h bacterial culture of *Agrobacterium tumefaciens* (At 10). Red-skinned  
122 potatoes were surface sterilized in 0.1% HgCl<sub>2</sub> solution and potato discs of size 8mm×4mm were  
123 prepared with the help of sterilized cork borer. Ten discs were placed on the agar plates along  
124 with 50  $\mu$ l of inoculum on the surface of each disc. After 21 days of incubation at 28°C, discs  
125 were stained with Lugol solution (10% KI & 5% I<sub>2</sub>) and tumors were counted on each disc. The  
126 tumor inhibition was calculated by formula, (Percentage inhibition = 100 – average number of  
127 tumors of sample/ average number of tumors of negative control × 100).

128 Antioxidant or prooxidant activity of the synthesized compounds was assessed by DNA damage  
129 assay [26]. Plasmid DNA (pBR322 Fermentas) with a concentration of 0.5  $\mu$ g/3 $\mu$ l was treated  
130 with three different concentrations of test samples (1000, 100, and 10 ppm). Fenton reaction was  
131 induced by addition of 30% H<sub>2</sub>O<sub>2</sub> (4  $\mu$ l) and 2 mM FeSO<sub>4</sub> (3  $\mu$ l) into the reaction mixture. Three  
132 controls, untreated pBR322 DNA as negative, DNA treated with compound (C+P), DNA treated  
133 with 2 mM FeSO<sub>4</sub> and 30% H<sub>2</sub>O<sub>2</sub> as positive control were run simultaneously. Each reaction  
134 mixture was incubated at 37°C for an hour. After incubation, the sample was loaded on a 0.9%

135 agarose gel and was visualized with Doc-IT (VWR). Estimation of antioxidant or pro-oxidant  
 136 effects on DNA was estimated on the basis of percentage increase or loss of a super-coiled  
 137 monomer, compared with the control.

138 Voltammetric studies (cyclic voltammetry (CV), differential pulse voltammetry (DPV) and  
 139 square wave voltammetry (SWV)) were conducted by using Eco Chemie Autolab PGSTAT 302  
 140 potentiostat/galvanostat (Utrecht, the Netherlands) with software version GPES 4.9. The  
 141 conventional three-electrode cell with Ag/AgCl(aq) as a reference, home-made platinum wire as  
 142 a counter electrode and a glassy carbon electrode (GCE) with surface area of 0.09 as a working  
 143 electrode was employed. The active surface area of GCE was polished with 0.25 m alumina  
 144 paste on a nylon buffing pad followed by rinsing with distilled water and DMSO. The  
 145 electrochemical behaviour of each compound (2mM) was investigated in argon saturated  
 146 H<sub>2</sub>O/DMF (1:9,v:v) solution containing 0.1M tetrabutylammoniumtetrafluoroborate  
 147 (TBATFB). Drug-DNA interaction studies by CV were carried out in aqueous-DMF mixture  
 148 (1/9,v/v) at a scan rate of 100 mV/s by the sequential addition of DNA.

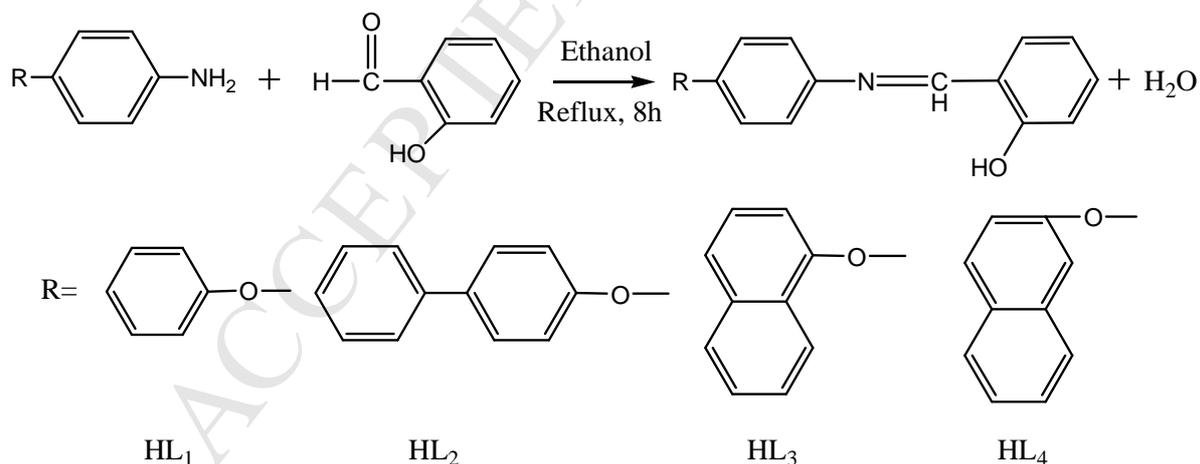

149

## 150 2.2 General procedure for the synthesis of ON donor Schiff bases (HL<sub>1</sub>-HL<sub>4</sub>)

151

152 ON donor Schiff bases (HL<sub>1</sub>-HL<sub>4</sub>) were synthesized by adopting the following general  
 153 procedure:

154 In a pre-backed two necked round bottom flask (250 ml) equipped with magnetic stirrer and  
 155 reflux condenser, the solution of salicylaldehyde was taken in dried ethanol. To this, solution of  
 156 corresponding amine in dried ethanol was added drop wise with constant stirring. The reaction  
 157 mixture was refluxed for 8 h under inert conditions using nitrogen. The progress of the reaction  
 158 was monitored by TLC. After the completion of the reaction the ethanol was removed by rotary  
 159 evaporator [27]. The solid product was recrystallized from ethanol (scheme 1).

160  
 161

163

#### 164 2.2.1. (E)-2-((4-phenoxyphenylimino)methyl)phenol (HL<sub>1</sub>)

165

166 (E)-2-((4-phenoxyphenylimino)methyl)phenol (HL<sub>1</sub>) was manufactured by refluxing equimolar  
167 quantities of 1-amino-4-phenoxybenzene 1.85 g (10 mmol) and 1.05 ml (10 mmol) 2-hydroxy  
168 benzaldehyde.

169 Color: yellow, Yield 90%, melting point 91<sup>0</sup>C. FTIR: (  $\nu$  /cm<sup>-1</sup>) 3405 (-OH), 1603, (-CH=N), <sup>1</sup>H  
170 NMR (300 MHz, CDCl<sub>3</sub>,  $\delta$  ppm):13.30 (s, 1 H, -OH), 8.65 (s, 1 H, -CH=N), 7.43-6.94 (13 H, m,  
171 Ar- H), <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>,  $\delta$  ppm): 162.13 (-C=N), 160.24-117.15 (18 C, Ar-C), MS  
172 (m/z): 289(M<sup>+</sup>) CHN found (calcd.) for C<sub>19</sub>H<sub>15</sub>NO<sub>2</sub> : C: 78.79 (78.89), H: 5.73 (5.19), N: 4.72  
173 (4.84).

174

175 2.2.2. (E)-2-((4-(4-biphenyloxy)phenylimino)methyl)phenol (HL<sub>2</sub>)

176

177 (E)-2-((4-(4-biphenyloxy)phenylimino)methyl)phenol (HL<sub>2</sub>) was synthesized by refluxing  
178 equimolar quantities of 4-(4-aminophenoxy) biphenyl 2.61 g (10 mmol) and 1.05 ml (10 mmol)  
179 2-hydroxy benzaldehyde.

180 Color: light yellow, Yield 92%, melting point 173<sup>0</sup>C. FTIR: (  $\nu$  /cm<sup>-1</sup>) 3400 (-OH), 1601 (-  
181 CH=N), <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>,  $\delta$  ppm):13.30 (s, 1 H, -OH),8.66 (s, 1 H, -CH=N), 7.63-  
182 6.95 (17 H, m, Ar- H), <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>,  $\delta$  ppm): 161.73 (-C=N), 160.15-117.28 (24  
183 C, Ar-C), MS (m/z): 365 (M<sup>+</sup>) CHN found (calcd.) for C<sub>25</sub>H<sub>19</sub>NO<sub>2</sub> : C: 82.15 (82.19), H: 5.58  
184 (5.20), N: 3.94 (3.84).

185

186 2.2.3. (E) - 2-((4-(naphthalen-1-yloxy)phenylimino)methyl)phenol (HL<sub>3</sub>)

187

188 (E) - 2-((4-(naphthalen-1-yloxy)phenylimino)methyl)phenol (HL<sub>3</sub>) was prepared by taking  
189 equimolar quantities of 1-(4-aminophenoxy) naphthalene 2.35 g (10 mmol) and 1.05 ml (10  
190 mmol) 2-hydroxy benzaldehyde.

191 Color: yellow, Yield 87%, melting point 105<sup>0</sup>C. FTIR: (  $\nu$  /cm<sup>-1</sup>) 3412 (-OH), 1613 (-CH=N), <sup>1</sup>H  
192 NMR (300 MHz, CDCl<sub>3</sub>,  $\delta$  ppm): 13.32, (s, 1 H, -OH), 8.65 (s, 1 H, -CH=N), 8.23-6.94 (15 H,  
193 m, Ar- H), <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>,  $\delta$  ppm): 162.27 (-C=N), 159.01-114.72 (22 C, Ar-C), MS  
194 (m/z): 339(M<sup>+</sup>) CHN found (calcd.) for C<sub>23</sub>H<sub>17</sub>NO<sub>2</sub> : C: 81.69 (81.41), H: 5.06 (5.01), N: 4.06  
195 (4.13).

196

197 2.2.4. (E)-2-((4-(2-naphthoxy)phenylimino)methyl)phenol (HL<sub>4</sub>)

198

199 (E)-2-((4-(2-naphthoxy)phenylimino)methyl)phenol (HL<sub>4</sub>) was synthesized by using equimolar  
200 quantities of 2-(4-aminophenoxy) naphthalene 2.35g (10 mmol) and 1.05 ml (10mmol) 2-  
201 hydroxy benzaldehyde.

202 Color: yellow, Yield 93%, melting point 120 <sup>0</sup>C. FTIR : (  $\nu$  /cm<sup>-1</sup>) 3408 (-OH), 1610 (-CH=N),  
203 <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>,  $\delta$  ppm):13.30 (s, 1H, -OH),8.68 (s, 1 H, -CH=N), 7.90-6.96 (15H,  
204 m, Ar- H), <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>,  $\delta$  ppm): 162.25 (-C=N), 161.08-114.27 (22 C, Ar-C),  
205 MS (m/z): 339(M<sup>+</sup>) CHN found (calcd.) for C<sub>23</sub>H<sub>17</sub>NO<sub>2</sub> : C: 81.39 (81.41), H: 5.75 (5.01), N:  
206 4.06 (4.13).

207

### 208 3 Results and Discussion

209

210 Schiff bases (HL<sub>1</sub>-HL<sub>4</sub>) have been successfully synthesised in a single step as described in  
211 experimental section and were characterised by spectroscopic, analytical, voltammetric and X-  
212 ray diffraction analysis. They are air stable under ambient conditions and soluble in common  
213 organic solvents such as C<sub>2</sub>H<sub>5</sub>OH, CH<sub>2</sub>Cl<sub>2</sub>, CHCl<sub>3</sub>, DMSO, and DMF. The synthesized Schiff  
214 bases (HL<sub>1</sub>-HL<sub>4</sub>) were tested for biological, voltammetric and DNA interaction studies by cyclic  
215 voltammetrically.

216

### 217 3.1 Spectral characterization

218

219 The structures of the synthesised compounds were established by means of spectral studies  
220 (FTIR, <sup>1</sup>H NMR, <sup>13</sup>C NMR and mass spectrometry), elemental analysis, and single crystal X-ray  
221 diffraction studies.

222 The FTIR spectral analysis of Schiff bases indicated the presence of all expected  
223 functionalities. Schiff bases having O-hydroxy group on an aldehyde can form intramolecular  
224 hydrogen bonding which affects ν(OH) vibration by shifting towards lower frequency with  
225 broadening. The extent of shift depends on the strength of hydrogen bonding. The FTIR spectra  
226 of these compounds exhibited the strong absorptions bands in the region of 1601-1613 cm<sup>-1</sup> due  
227 to azomethine bond (CH=N). The hydroxyl groups (-OH) of the Schiff bases showed broad  
228 absorption bands in the region of 3400-3412 cm<sup>-1</sup>. The disappearance of peaks in the region  
229 3391-3468 (asymmetric) and 3315-3372 (symmetric) cm<sup>-1</sup> for -NH<sub>2</sub> moiety confirmed the  
230 conversion of amino group into azomethine bond. They also exhibited absorption bands of C-O-  
231 C vibrations in the region of 1244-1260 cm<sup>-1</sup> [28]. The FTIR spectra of Schiff bases as presented  
232 in Fig. S1(a-d).

233 The <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra of all the Schiff bases are consistent with the proposed  
234 molecular structures. The <sup>1</sup>H NMR spectra showed the characteristic azomethine singlet in the  
235 region of 8.68-8.65 ppm. Phenyl protons were present in all the compounds which were verified  
236 by the appearance of multiplets in the range of 7.43-6.94 (HL<sub>1</sub>), 7.63-6.95 (HL<sub>2</sub>), 8.23-6.94  
237 (HL<sub>3</sub>) and 7.90-6.96 (HL<sub>4</sub>) ppm, according to the substituents attached. The resonance signals  
238 observed around 13.30-12.14 were assigned to phenolic proton as shown in Fig. S2(a-d).

239 <sup>13</sup>C NMR spectra of Schiff bases show all the characteristic signals of azomethine and aromatic  
240 carbon atoms in their respective ranges of chemical shift values. Azomethine carbon resonated  
241 around 162 ppm. The resonance signals observed around 160, 155-150 and 141 ppm were  
242 assigned to C-OH, C-O-C and C-N carbons respectively. The rest of the peaks from 146-110  
243 ppm were due to aromatic carbon atoms of Schiff bases as displayed in Fig. S3(a-d).

244 The mass spectral data of the Schiff bases justified their formation as their molecular ion peaks  
245 were obtained at (m/z) 289, 365, 339 and 339 respectively as revealed in Fig. S4(a-d).

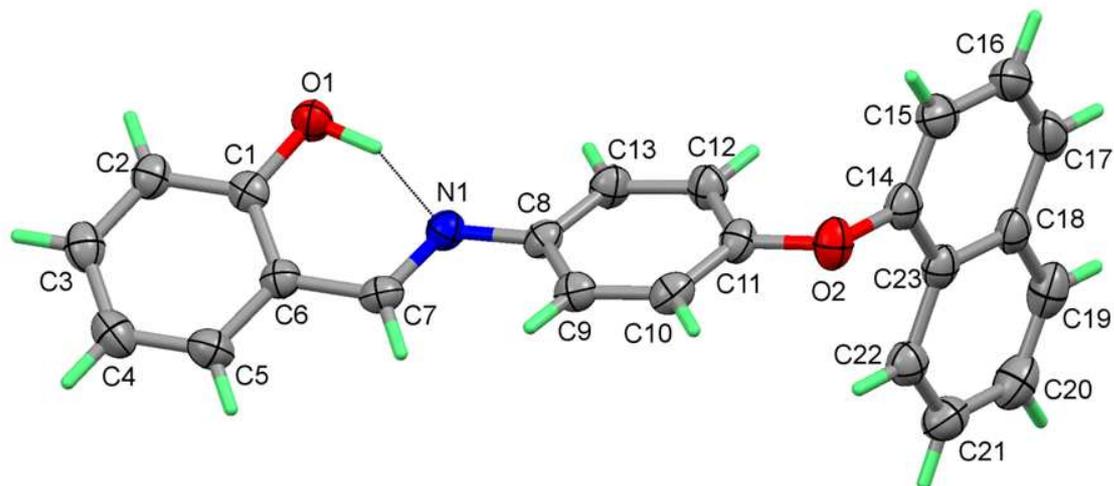

246

### 247 3.2 X- ray structure analysis of HL<sub>3</sub>

248

249 The single crystals of Schiff base (HL<sub>3</sub>) for X-ray crystallographic analysis were grown by the  
250 slow evaporation of its ethanolic solution at room temperature. A single suitable crystal was  
251 selected for X-ray diffraction analysis and was mounted on Bruker Apex II CCD diffractometer.  
252 The crystal was kept at 150(2)K during analysis. A perspective diagram of HL<sub>3</sub> is shown in Fig.  
253 1. There are no unusual bond lengths; the phenol and anthracene rings are inclined at 30.23(8)<sup>o</sup>  
254 and 89.64(4)<sup>o</sup> to the central phenyl ring, respectively and the phenol group makes an  
255 intramolecular hydrogen bond to the imine nitrogen (O1 - N1, 2.5591(18)Å). There is some π...π

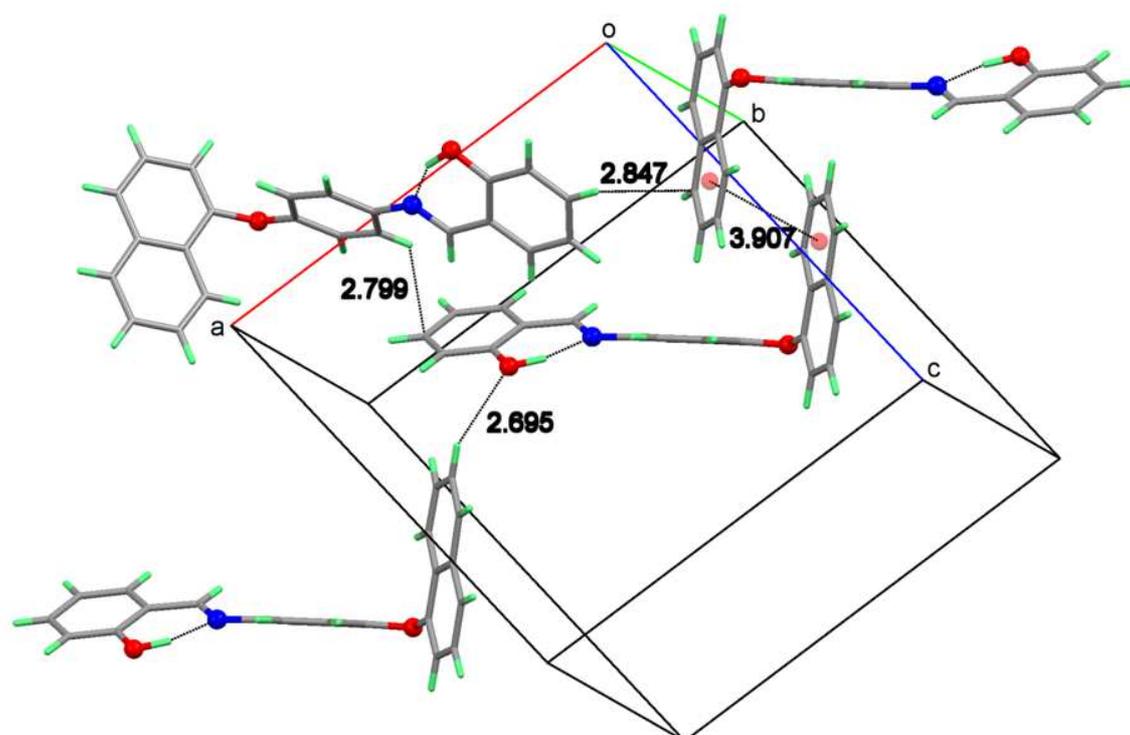

256 stacking between anthracene groups, but most of the intermolecular interactions are of the C-H $\cdots$  $\pi$   
257 type as shown in Fig. 2.  
258

259

260

261 **Fig.1** Perspective diagram of HL<sub>3</sub> showing 50% probability ellipsoids.

262

263

264 **Fig. 2** Intermolecular interactions in HL<sub>3</sub>

265 Crystal data and refinement details are listed in Table 1. Selected bond lengths and angles for  
266 HL<sub>3</sub> are summarized in Table 2 and hydrogen bonding parameters in Table 3.

267 **Table 1.** Crystal data and structure refinement for HL<sub>3</sub>

268	Empirical formula	C <sub>23</sub> H <sub>17</sub> N O <sub>2</sub>

308 3.3. Pharmacological studies

309

310 3.3.1. Brine shrimp cytotoxic assay

311

312 Brine shrimp cytotoxicity assay is a pre-screen test to observe the bioactive nature of  
 313 compounds. The compounds HL<sub>1</sub> and HL<sub>3</sub> showed significant activity against brine shrimp  
 314 nauplii to be highly active with LD<sub>50</sub> values 0.18 and 0.06  $\mu\text{g/ml}$  respectively. This cytotoxic  
 315 action of a drug is simply provided by disturbing the basic mechanisms concerned with mitotic  
 316 activity, cell growth, function and differentiation (Table 4).

317 **Table 4.** Results of cytotoxicity, potato disc antitumor and inhibition of hydroxyl free radical  
 318 induced DNA damage assays.

Compound	Cytotoxic activity		Antitumor activity			DNA protection activity		
	LD <sub>50</sub> value ( $\mu\text{g/ml}$ )	percentage inhibition $\pm$ SD		IC <sub>50</sub> ( $\mu\text{g/ml}$ )	10( $\mu\text{g/ml}$ )	100( $\mu\text{g/ml}$ )	1000( $\mu\text{g/ml}$ )	
		10( $\mu\text{g/ml}$ )	100( $\mu\text{g/ml}$ )					1000( $\mu\text{g/ml}$ )
HL <sub>1</sub>	0.18	40 $\pm$ 1.8	82.5 $\pm$ 0.8	95 $\pm$ 0.4	14.20	+	+++	+++
HL <sub>3</sub>	0.06	55 $\pm$ 1.4	75 $\pm$ 1.3	100 $\pm$ 0	4.54	+	+++	+++

319 DNA: Deoxyribonucleic acid; LD<sub>50</sub>: lethal dose 50 or median lethal dose; SD: standard  
 320 deviation; IC<sub>50</sub>: half maximal inhibitory concentration

321

322 3.3.2. Potato disc antitumor assay

323

324 The compounds were screened for possible antitumor activity by using potato disc antitumor  
 325 assay and results are summarized in Table 4. The results of compounds HL<sub>1</sub> and HL<sub>3</sub> showed  
 326 significant antitumor activity with IC<sub>50</sub> values 14.20 and 4.51  $\mu\text{g/ml}$  respectively. It is thought  
 327 that these compounds at different doses may be used against different cancer-chemopreventive  
 328 models and may appear to contrive safer drugs for future.

329

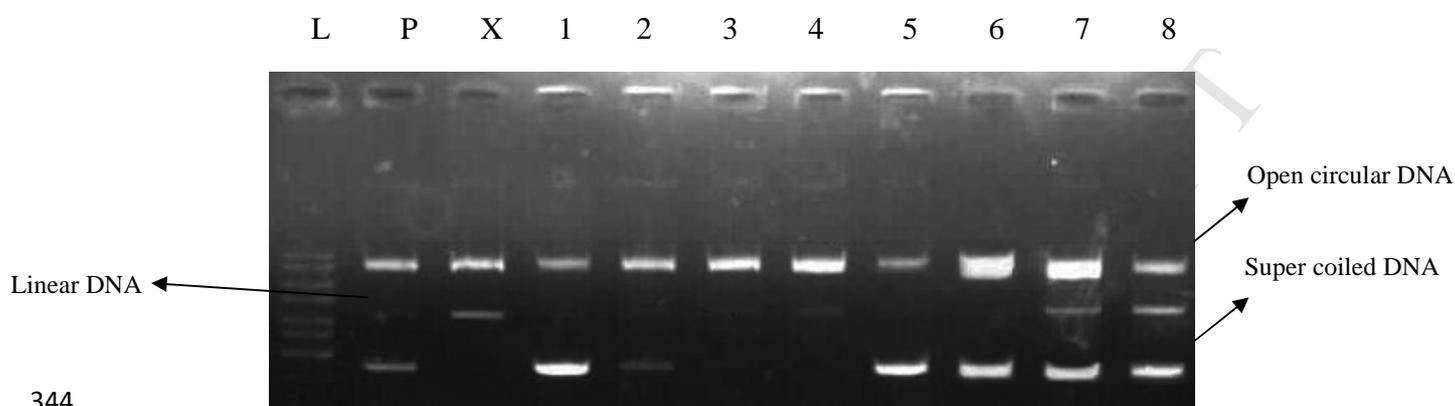

330 3.3.3. DNA protection assay

331

332 To check the antioxidant and pro-oxidant behavior of compounds free radical induced DNA  
 333 damage assay was performed. With the attack of  $\cdot\text{OH}$  produced from the Fenton reaction,  
 334 supercoiled plasmid DNA is broken into two forms, including open circular (OC) and linear  
 335 form (linear). By analyzing the intensity of bands formed on 1% agarose gel, results are noted  
 336 and tabulated (Fig.3). The compounds HL<sub>1</sub> and HL<sub>3</sub> showed moderate protection at 1000  $\mu\text{g/ml}$   
 337 and 100  $\mu\text{g/ml}$  concentrations; while slight protection at 10  $\mu\text{g/ml}$  concentration. So, it was  
 338 concluded that these compounds showed DNA protection in concentration dependent manner i.e.  
 339 DNA protection increased with the increase in concentration of the test compound.

350 μg/ml of HL<sub>2</sub>; control for the pro-oxidant effect of the compound on DNA, 6 = plasmid + 1000  
351 μg/ml of HL<sub>2</sub> + FeSO<sub>4</sub> + H<sub>2</sub>O<sub>2</sub>, 7 = plasmid + 100 μg/ml of HL<sub>2</sub> + FeSO<sub>4</sub> + H<sub>2</sub>O<sub>2</sub>, 8 = plasmid + 10  
352 μg/ml of HL<sub>2</sub> + FeSO<sub>4</sub> + H<sub>2</sub>O<sub>2</sub>

353

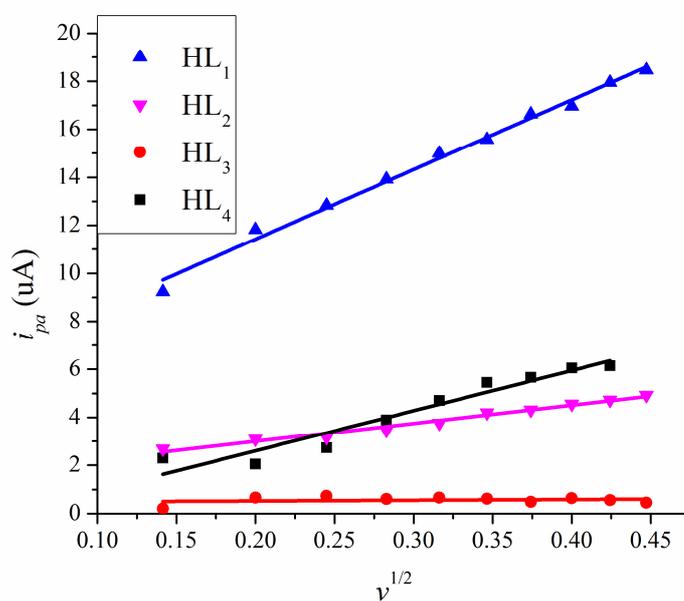

### 354 3.2 Voltammetric studies.

355

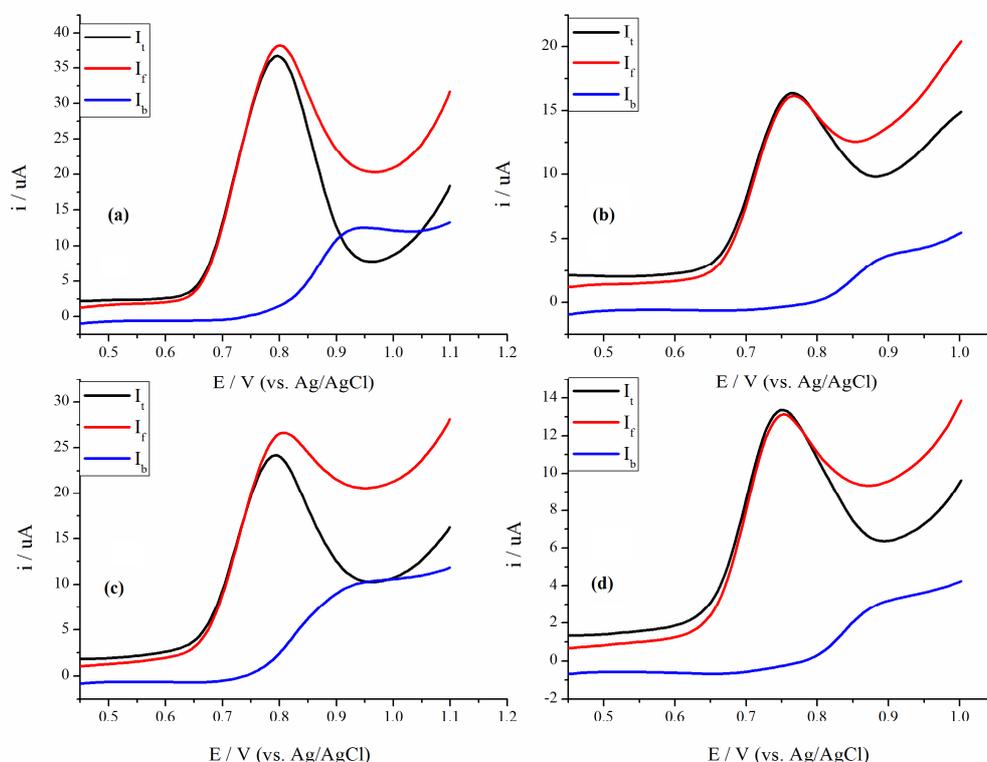

356 Electrochemical behaviour of the Schiff bases (HL<sub>1</sub>-HL<sub>4</sub>, 2mM) was investigated by employing  
357 three voltammetry techniques (CV, DPV and SWV) in oxygen free atmosphere in DMF solution.  
358 The cyclic voltammograms are displayed in Fig. 4. During anodic scan only one oxidation peak  
359 was observed for all the four Schiff bases, which appears in the range of 0.815 to 0.844 V,  
360 without corresponding reduction peak on the backward scan. This describes the irreversible  
361 oxidation of OH moiety present on the Schiff base molecule. To inspect the adsorption of the  
362 oxidation product, which is likely in such type of compounds, the successive scans were  
363 recorded at constant potential scan rate (100 mVs<sup>-1</sup>). A systematic decrease in peak current was  
364 observed in following cycles for all the compounds revealing adsorption of oxidation product  
365 while hindering the further electron transfer process on the surface of working electrode. The  
366 GCE was very carefully renewed each time for a new compound. While increasing the scan rate  
367 for all the Schiff bases, it was found that oxidation peak current increases linearly with square  
368 root of scan rates as shown in Fig. 5 and follows the Randles-Sevcik equation of an irreversible  
369 process. The details about the equation and parameters are given in our earlier papers[29-  
370 32]. The diffusion coefficients evaluated from the slope of anodic peak current vs. square root of  
371 scan rate were found to be  $4.65 \times 10^{-6}$ ,  $3.18 \times 10^{-7}$ ,  $5.15 \times 10^{-10}$  and  $1.55 \times 10^{-7}$  for HL<sub>1</sub>, HL<sub>2</sub>, HL<sub>3</sub>  
372 and HL<sub>4</sub> respectively. The values depict that the ET process is diffusion controlled.

373  
 374 **Fig.4** Cyclic voltammograms of Schiff bases HL<sub>1</sub>, HL<sub>2</sub>, HL<sub>3</sub> and HL<sub>4</sub> (2mM each) recorded in  
 375 their argon saturated H<sub>2</sub>O/DMF (1/ 9; v/v) + 0.1M TBATFB solution at 100 m Vs<sup>-1</sup>(Vs<sup>-1</sup>)<sup>1/2</sup> scan  
 376 rate at 25°C.

377  
 378 **Fig. 5** Plots of anodic peak current ( $i_{pa}$ ) with square root of scan rate  $v^{1/2}/ (Vs^{-1})^{1/2}$  for HL<sub>1</sub>, HL<sub>2</sub>,  
 379 HL<sub>3</sub> and HL<sub>4</sub>.  
 380 To further confirm the irreversibility of the ET process SWV was run. The resultant  
 381 voltammograms of HL<sub>1</sub>, HL<sub>2</sub>, HL<sub>3</sub> and HL<sub>4</sub> are shown in Fig. 6 (A-D). The absence of reduction  
 382 current in all the four cases evidently indicates the complete irreversible nature of ET process as  
 383 shown in CV results.

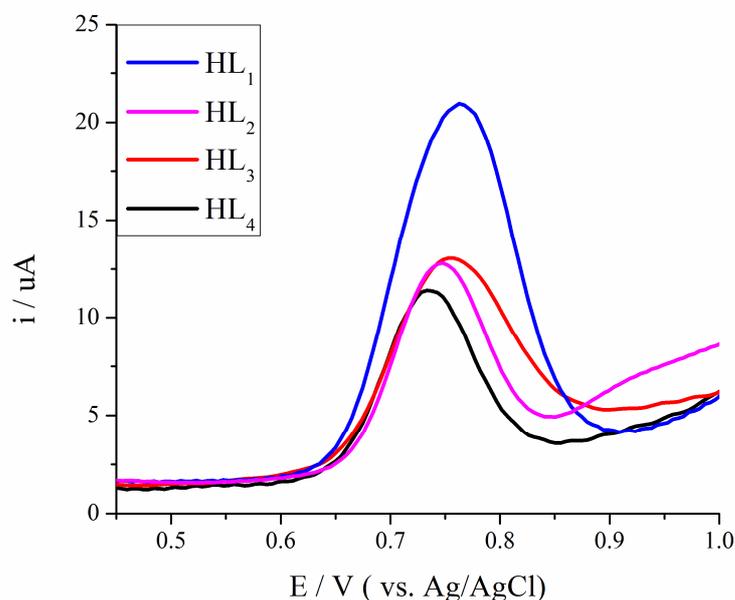

384

385 **Fig.6** Square wave voltammograms of compound, HL<sub>1</sub>(a), HL<sub>2</sub>(b), HL<sub>3</sub>(c) and HL<sub>4</sub>(d) (2 mM  
 386 each) recorded at GCE in argon saturated H<sub>2</sub>O/DMF (1/ 9; v / v) + 0.1 M TBATFB solution at  
 387 25°C, E<sub>sw</sub> =5 mV frequency = 10 Hz . Pulse amplitude =25mV. The symbols are; I<sub>t</sub>- total  
 388 current, I<sub>f</sub> – forward current, I<sub>b</sub> –backward current.

389

390 DP voltammograms of the Schiff bases, displayed in Fig. 7, were recorded to estimate the  
 391 number of electrons involved in the electrooxidation. The recorded peak currents are in the order  
 392 of HL<sub>1</sub>> HL<sub>3</sub>> HL<sub>2</sub>>HL<sub>4</sub> same as observed in CV studies indicating the enough sensitivity of CV  
 393 for these compounds in the given time scale. The full peak width at half peak current(W<sub>1/2</sub>)  
 394 values are 122, 88, 117 and 88 mV for HL<sub>1</sub>, HL<sub>2</sub>, HL<sub>3</sub>and HL<sub>4</sub>,respectively and are close to the  
 395 theoretical value of 90 mV for ET process involving one electron only. Hence, it is concluded on  
 396 the basis of voltammetry results that there is single electrophore in the studied Schiff bases  
 397 offering one ET irreversible diffusion controlled oxidation process. Corollary of this result is that  
 398 the electro-oxidised species will act as a good nucleophile for the DNA molecules.

399

400 **Fig.7** Differential pulse voltammograms of the Schiff bases with 2 mM each recorded in argon  
 401 saturated H<sub>2</sub>O /DMF(1/9; v /v) + 0.1M TBATFB solution at 25°C.

402

#### 403 4 DNA-drug interaction studies

404

405 The CV was employed to envisage the role of Schiff bases as drug molecules against DNA  
 406 degradation. The characteristic parameters of the peak potential and peak current of a compound  
 407 are prone to change on addition of DNA if the former is 'active'. The variation in peak current  
 408 with varying concentration of DNA at fixed concentration of a Schiff base was utilized to  
 409 determine the quantitative binding parameters (Fig. 8, Table 4) whereas the shift in peak  
 410 potential was used to get an idea about the modes of interaction.

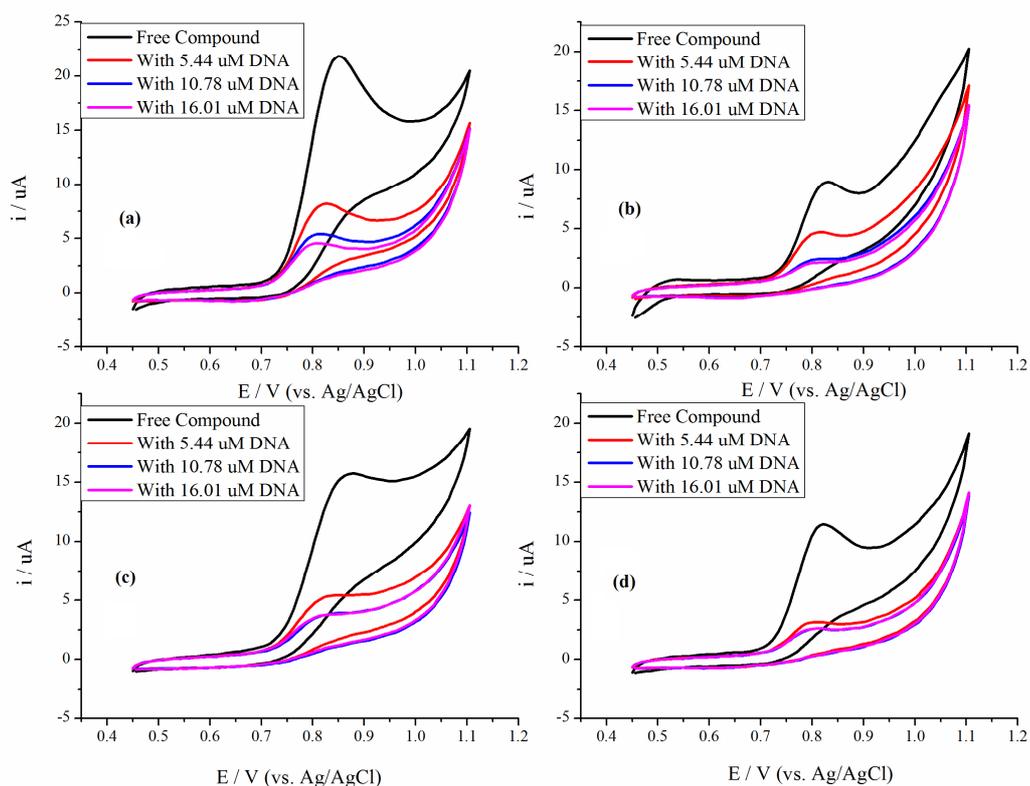

411 The values of binding constant (K) were calculated from equation 1 which determines the  
 412 strength of binding of a molecule to the DNA.

$$413 \frac{1}{[DNA]} = K (1-A) / (1-I/I^0) - K \quad (1) \quad [33]$$

414 Where A is an empirical constant, I<sup>0</sup> and I are peak currents in the absence and presence of DNA,  
 415 respectively.

416 From Fig. 8 and the tabulated data (Table 4) it is evident that on addition of first increment of  
 417 DNA (5.44 μM) to the electro-oxidised product of the Schiff base there is a marked decrease in  
 418 the peak current which is about two third of the original peak current. To ensure that this  
 419 decrease is not due to adsorption of the molecule on the electrode surface, the GCE surface was  
 420 renewed each time before running the next increment of DNA. On the other hand the addition of  
 421 DNA caused a very small negative shift in the peak potential even up to the 16.01 μM DNA. The  
 422 negative shift in peak potential is revealing the electrostatic interaction between the  
 423 electrooxidised electrophile of Schiff base and the negative phosphate component of DNA  
 424 molecules. The result is in agreement to that conferred above in DPV analysis of the compounds.  
 425 The sequential drop in peak current has attributed the decrease in free drug concentration due to  
 426 formation of slow diffusing Schiff base-DNA adducts. Formation of this slow diffusing complex

427 is also evident from lowering in diffusion coefficient values upon the addition of DNA as  
 428 compared to free compounds as shown in Table 4. The binding constant values given in Table 4  
 429 are in the range of the order of  $\approx 10^4 \text{ M}^{-1}$ . These moderately high values ( $K = 3.6 \times 10^4 \text{ M}^{-1}$  for  
 430 cisplatin[34]) suggest that ON donor Schiff bases are efficient DNA binders.  
 431 As a whole it can be safely interpreted from the results that the investigated Schiff bases possess  
 432 sufficient potential to be pursued as drug molecules whereas they were found interacting with  
 433 DNA while being consumed chemically and partially due to electrostatic linkage.  
 434

435  
 436  
 437 **Fig.8** Cyclic voltammograms of 2mM  $\text{H}_2\text{O}/\text{DMF}$  (1/ 9; v/v) of  $\text{HL}_1$  (a),  $\text{HL}_2$  (b),  $\text{HL}_3$  (c) and  $\text{HL}_4$   
 438 (d) (—) without DNA, (—) in the presence of 5.44  $\mu\text{M}$  DNA, (—) 10.78  $\mu\text{M}$  DNA and (—)  
 439 16.01  $\mu\text{M}$  DNA on glassy carbon electrode at scan rate of 100 mV/s.

 450 DNA: Deoxyribonucleic acid; D<sub>o</sub>: diffusion coefficient; E<sub>p</sub>: peak potential; K: complex stability  
 451 constant.

452  
 453 **4 Conclusions**

454 Four novel ON donor Schiff bases (HL<sub>1</sub>-HL<sub>4</sub>) have been successfully synthesized and  
 455 characterized by various spectroscopic, analytical and electro-analytical techniques. Single  
 456 crystal X-ray diffraction analysis of Schiff base (HL<sub>3</sub>) reveals intra (hydrogen bonding) and inter  
 457 molecular interactions(C-H...π type, π...π stacking between anthracene groups).The biological  
 458 findings showed significant activity in inhibiting the tumour formation by *A. tumefaciens* on  
 459 potato discs. These compounds also have potential to prevent H<sub>2</sub>O<sub>2</sub> induced oxidative damage to  
 460 pBR322 DNA. Overall these compounds displayed a variant degree of activity in all the assays,  
 461 further investigations are required to explore the exact mechanism of biological activities which  
 462 may be helpful to explore new and alternative chemotherapeutic agent(s) in clinical implications.  
 463 The compounds were found to respond irreversible one electron diffusion controlled  
 464 electrooxidation on glassy carbon electrode. Further, they were found to interact to DNA in  
 465 electrooxidised form through combined mode of groove binding and electrostatically with  
 466 sufficiently good strength to be pursued further as drug molecules.

**Highlights**

- Four novel ON donor Schiff bases were synthesized with yields around 90%.
- Exhibited strong  $\bullet\text{OH}$  scavenging activity in concentration dependent manner.
- Voltammetry revealed irreversible single electron oxidation with  $D_0 \sim 10^{-10} - 10^{-6} \text{ cm}^2 \text{ s}^{-1}$ .
- Anticancerous nature, intercalating with DNA having binding constants of  $10^4 \text{ M}^{-1}$ .
