Abstract

Novel difluorinated cyclopropane nucleoside analogues possessing both two vicinal hydroxymethyl groups and a methylene spacer between the base and the ring were synthesized starting from 1,3-dibenzyloxy-2-propanol. After oxidation, olefination, reduction and acetylation the target molecules were obtained by difluorocyclopropanation, deacetylation and Mitsunobu reactions followed by two consecutive deprotection steps. © 1998 Elsevier Science Ltd. Introduction

A large number of cyclopentanoid or cyclobutanoid carbocyclic nucleoside analogues has been synthesized as potential chemotherapeutic agents [1-4]. More recently, cyclopropane derived nucleosides have been in the focus of interest [5-10]; thus, analogues possessing an additional spacer or an unsaturated group [11, 12] between the cyclopropane unit and the heterocycle as well as compounds with an (in)direct attachment of the heterocycle but with two geminal or vicinal hydroxymethyl units at the cyclopropane skeleton [13-17] have shown promising antiviral activity. Although the incorporation of one or two fluorine substituents is known to be of advantage both for an improved activity, higher bioavailability as well as for causing a retarded metabolism of several drugs, only very recently, the first successful synthesis of several difluoro-cyclopropyl homo-nucleosides of type A has been reported [18]. The general principle used for the synthesis of compounds of type A could be used for the straightforward synthesis of compounds of type B.

Results and Discussion

Our approach to the target compounds started from easily accessible 1.3-dibenzyloxy-2-propanol (1) [19] that was oxidized to the corresponding ketone 2 [20] with the 2.2.6.6. tetramethyl-piperidin-1-oxyl radical (TEMPO). Although a broad variety of different oxidants have been tested, the TEMPO [21, 22] mediated synthesis of 2 has been found to be superior even to periodinane, N-bromo-succinimide-dimethylsulfoxide, perruthenate, pyridinium chlorochromate and pyridinium dichromate. Olefination [23] of 2 furnished the alkene 3 that upon treatment with diisobutyl aluminium hydride (DIBAH) at -40°C [23] resulted in the formation of alcohol 4 without affection of the double bond. Alcohol 4 was acetylated and the acetate 5 was subjected to a difluoro-cyclopropanation reaction using sodium chlorodifluoro acetate in diglyme at 190°C to afford the cyclopropane 6. Compound 6 is characterized in its ¹⁹F NMR spectrum by the presence of two signals at $\delta = -136.00$ and -147.36 ppm showing a ${}^{2}J_{\rm FF} = 164.5$ Hz. The quaternary carbon bearing the two diastereotopic fluorine substituents is found in the ¹³C NMR spectrum at $\delta = 114.27$ ppm showing $J_{C,F(1)} = 286.7$ and $J_{C,F(2)} =$ 292.9 Hz. Treatment of 6 with catalytic amounts of sodium methoxide in methanol gave very smoothly 92% of the key intermediate 7 that is characterized in its IR spectrum by the presence of a broad line at v = 3662 cm⁻¹ resulting from the presence of the hydroxy group; in addition, in the ¹H NMR spectrum a signal exchangeable with D₂O is found at $\delta = 2.92$ ppm. The two dibenzyloxymethyl groups are diastereotopic showing two independent AB systems in the ¹H NMR spectrum at $\delta = 3.63$ and 3.88 ppm ($J_{A,B}= 12.65$ Hz, CH₂O_{trans}) and δ = 3.24 and 3.63 ppm ($J_{A,B}$ = 10.55 Hz, CH₂O_{cis}), respectively.

Treatment of 7 with triphenylphosphine (TPP), diethyl azodicarboxylate (DEAD) and N³-benzoyl-thymine under Mitsunobu conditions [18, 24] afforded 8 whose debenzoylation with ammonium hydroxide for 12 h at room temperature gave 9 that was debenzylated with *Pearlman*'s catalyst using cyclohexene as a hydrogen donor to afford the thymine analogue 10 in 63% yield. 10 shows in the ¹⁹F NMR spectrum two signals at $\delta = -130.71$ and $\delta = -140.97$ ppm with a ²*J*_{F,F} = 160.8 Hz; the signal for the CH₂-N moiety is found in the ¹³C NMR spectrum at $\delta = 41.15$ ppm showing a ³*J*_{C,F} = 4.0 Hz. The assignment of all signals was performed by 2D homo- and heteronuclear COSY as well as 2D-NOESY experiments.

Similarly, the Mitsunobu reaction of 7 with N³-benzoyl-uracil gave 11 in 84% yield. Consecutive deprotection as above afforded 12 and finally the uracil analogue 13. Mitsunobu reaction of 7 with N³-benzoyl-5-fluoro-uracil, TPP and DEAD gave 67% of 14 whose debenzoylation yielded 92% of 15 that was debenzylated to afforded the target compound 16.

Compound 16 is characterized in its ¹⁹F NMR spectrum by the presence of three signals at $\delta = -134.27$, -144.44 and -167.49 ppm the latter of which can be assigned to the fluoro substituent at the 5'-position of the heterocycle.

Finally, an adenine analogue was prepared by the same strategy starting from 7 that was subjected to a Mitsunobu reaction to afford 17 in 72% yield. Debenzylation of 17 under the usual conditions gave the adenine analogue 18.

The synthesis of enantiomerically pure analogues, their (tri)-phosphates as well as their incorporation in DNA and RNA fragments is presently investigated in our laboratories.
