#### ABSTRACT

 $\beta$ -Nitrostyrenes react with o-lithiobenzonitrile, generated from the requisite aryl bromide at -100 °C by bromine–lithium exchange with n-butyllithium in THF, to afford 2-nitro-3-phenyl-3H-inden-1-ylamines resulting from 1,4-addition to the  $\beta$ -nitrostyrene followed by intramolecular capture of the resultant nitronate anion by the o-tho-cyano functional group.

The construction of benzo-fused polycyclic carbocycles and heterocycles via low-temperature reaction of aryllithium reagents containing electrophilic ortho-substituted functional groups, a method known as the Parham cyclization, was developed three decades ago and has been widely accepted as a powerful tool for organic synthesis. A sampling of electrophilic functional groups used in these reactions as external electrophiles includes ketones, aldehydes, nitriles, imines, isocyanates, and anhydrides (Scheme 1).

Reactions of  $\beta$ -nitrostyrenes and other nitroalkenes as Michael acceptors with a variety of organometallic reagents have been well documented. More recently, the ability of  $\beta$ -nitrostyrenes and nitroalkenes to undergo conjugate additions with organolithium reagents has been utilized as a key carbon–carbon bond-forming step in the synthesis of a variety of cyclic ring systems. Paulson and Stubbe described the first known reaction of a Parham-type substrate (the bromine–lithium–exchanged intermediate of **4**) with nitroalkene **5** as a Michael acceptor in the key step toward the construction of a ring system in the total synthesis of (+)-lycoricidine (**7**) (Scheme 2).  $^{10}$ 

We wish to report the first example of the reaction of an ortho-cyano-functionalized aryllithium reagent with a β-nitrostyrene and concomitant intramolecular capture of the resultant lithium nitronate to afford cyclized products, 2-nitro-3-phenyl-3H-inden-1-ylamines, in a single-pot procedure. The halogenlithium exchange chemistry of the substrate chosen for this study, 2-bromobenzonitrile (8), has been well documented.4 Thus, reaction of 2-bromobenzonitrile with *n*-butyllithium in THF under nitrogen at -95 to -100 °C generates the corresponding aryllithium which is then quenched with the β-nitrostyrene 9 followed by warming to room temperature (Scheme 3). Workup provides the 2-nitro-3-aryl-3*H*-inden-1-ylamines 11 in moderate-good yields (Table 1).<sup>11</sup> Using 2-methoxy-βnitrostyrene as the electrophile in the reaction sequence resulted in the formation of 12d as a minor by-product along with **11d**. A possible rationale for this observation may be related to the stability of the methoxy-chelated intermediate 10d (Fig. 1). At any rate, the uncyclized Michael adduct 12 can be isolated as the major product upon low temperature quenching with CH<sub>3</sub>OH.<sup>12</sup> The <sup>1</sup>H NMR spectra of inden-1-ylamines

12

11a–d reveal two –NH protons which are non-equivalent, presumably due to intramolecular hydrogen bonding of the enamino protons with the adjacent nitro group. <sup>13</sup> Future work will address the scope and limitations of Michael addition chemistry of  $\beta$ -nitrostyrenes with other Parham substrates and applications to total synthesis.

### Acknowledgments

We wish to thank The College of New Jersey for their generous support of this work.
