Received July 8, 1998

Summary: The allenylidene ligand of $[Ru(\eta^5-C_5H_5)\{C=C=CPh_2\}(CO)(PPr^i_3)]BF_4$ adds $PHPh_2$, $PMePh_2$, and PPh_3 selectively at the C_{α} atom, whereas OH^- and $[OMe]^-$ are added at the C_{γ} atom.

EHT-MO calculations on transition-metal allenylidene complexes indicate that the C_{α} and C_{γ} atoms of the allenylidene ligands are electrophilic centers and that the C_{β} atom is nucleophilic.¹ There are marked differences in reactivity depending upon the particular metallic fragment which stabilizes the allenylidene unit. This is nicely illustrated by the behavior of diphenylallenylidene in iron triad complexes. For example, Os- $(\eta^5 - C_5 H_5)Cl(C = C = CPh_2)(PPr_{3}^{i})$ is nucleophilic and reacts with HBF₄ and dimethyl acetylendicarboxylato to afford $[Os(\eta^5-C_5H_5)Cl(CCH=CPh_2)(PPr^i_3)]BF_4$ and $Os(\eta^5-C_5H_5)Cl(CCH=CPh_2)(PPr^i_3)]BF_4$ C_5H_5)Cl{C=C(CO_2Me)C(CO_2Me)=C=CPh_2}(PPrⁱ₃).² In contrast, the cationic compounds $[Os{C[C(O)OMe=$ CH_2 (C=C=CPh₂)(CO)(PPrⁱ₃)₂ BF₄,³ [Ru(η^5 -C₉H₇)(C= C=CPh₂)L₂]PF₆ (L₂ = 2 PPh₃, dppe, dppm), 1c,4 [RuCl(C= $C=CPh_2)(dppm)_2]PF_{6,5} [Ru(\eta^5-C_nH_m)(C=C=CPh_2)(PPh_3) \{\kappa^{1}-Ph_{2}PCH_{2}C(O)Bu^{t}\}$]PF₆ (C_nH_m = C₅H₅, C₉H₇),⁶ and $[RuCl(C=C=CPh_2){N(CH_2CH_2PPh_2)_3}]PF_6^7$ are electrophilic and react with RLi and Na[OCH₃] to give alkynyl derivatives resulting from regioselective additions at the C_{γ} atom of the allenylidene.

Diphenylallenylidene groups stabilized by less basic metallic fragments, such as $[Ru(\eta^5-C_5H_5)(CO)(PPr_{i_3})]^{+,8}$

[Ru(η^5 -C₉H₄Me₃)(CO)(PPh₃)]^{+,9} and [RuCl(η^6 -C₆H₄X₂)-(PMe₃)]⁺ (X = H, Me),¹⁰ show stronger electrophilic character and add alcohols at the C_{α}-C_{β} double bond of the allenylidene to afford α , β -unsaturated alkoxycarbene derivatives.

The reactivity of these allenylidene complexes toward phosphines⁴ seems to be controlled not only by the metallic fragment but also by the cone angle of the phosphine. This may be the reason that reactions with phosphines bulkier than PMe_2Ph have not been previously observed.

We report herein that PHPh₂ adds regioselectively to the C_{α} atom of the allenylidene ligand in [Ru(η^{5} -C₅H₅)-(C=C=CPh₂)(CO)(PPrⁱ₃)]BF₄ (**1**) to afford adduct **2** according to Scheme 1. Characteristic spectroscopic features of **2** are the C=C=C stretching frequency in the IR spectrum at 1884 cm⁻¹ and the three resonances in the ¹³C{¹H} NMR spectrum at 215.7, 104.5, and 71.8 ppm for the C_{β}, C_{γ}, and C_{α} allenyl carbon atoms. Complex **2** reacts with Et₃N in toluene to afford the neutral allenyl-phosphine derivative Ru(η^{5} -C₅H₅)-{C(PPh₂)=C=CPh₂}(CO)(PPrⁱ₃) (**3**), which regenerates **2** by protonation with HBF₄·OEt₂. A view of the molecular geometry of **3** is shown in Figure 1.

Figure 1. Molecular diagram of complex **3**. Selected bond lengths (Å) and angles (deg): Ru(1)-P(1) 2.325(2), Ru(1)-C(1) 2.139(5), C(1)-C(2) 1.292(7), C(2)-C(3) 1.333(7), C(3)-C(4) 1.478(7), C(3)-C(10) 1.518(7), P(2)-C(1) 1.827(5), P(2)-C(16) 1.841(5), P(2)-C(22) 1.840(5); Ru(1)-C(1)-C(2) 122.6(4), Ru(1)-C(1)-P(2) 117.0(2), C(1)-C(2)-C(3) 178.7(5), C(2)-C(3)-C(4) 123.4(4), C(2)-C(3)-C(10) 119.1(4), C(1)-P(2)-C(16) 106.6(2), C(1)-P(2)-C(22) 103.4(2).

The geometry around the ruthenium center in **3** is close to octahedral, with the cyclopentadienyl ligand occupying three sites of a face. The Ru-C(1) distance [2.139(5) Å] is that expected for a Ru–Csp² single bond and comparable to the related distance in alkenylruthenium complexes.¹¹ The C(1)–C(2) [1.292(7) Å] and C(2)-C(3) [1.333(7) Å] bond lengths, as well as the C(1)-C(2)-C(3) angle [178.7(5)°], which are in agreement with those reported for other transition-metal compounds of this type,¹² strongly support the allenyl formulation.¹³ In accordance with the structure shown in Figure 1, the IR spectrum of **3** shows the characteristic C=C=C stretching frequency at 1867 cm⁻¹, and the ${}^{13}C{}^{1}H$ NMR spectrum contains the three resonances corresponding to the $C_\beta,$ $C_\gamma,$ and C_α atoms at 200.0, 99.1, and 84.3 ppm.

Complex **3** reacts with MeI to give the I⁻ salt of the allenyl-phosphonio cation $[Ru(\eta^5-C_5H_5)\{C(PMePh_2)=C=CPh_2\}(CO)(PPr^i_3)]^+$ (**4**). The $[BF_4]^-$ salt is obtained by direct reaction of **1** with PMePh₂ in CH₂Cl₂ as solvent. Similarly, treatment of **1** with PPh₃ affords $[Ru(\eta^5-C_5H_5)\{C(PPh_3)=C=CPh_2\}(CO)(PPr^i_3)]BF_4$ (**5**). The identity of **4** and **5** are confirmed by a comparison of spectroscopic data with that for **2** and **3** (see Experimental Section).

Figure 2. Partially optimized structures of $\operatorname{Ru}(\eta^5-C_5H_5)$ -{C(OMe)=C=CH₂}(CO)(PH₃) (**a**) and $\operatorname{Ru}(\eta^5-C_5H_5)$ (C=CC-(OMe)H₂}(CO)(PH₃) (**b**) obtained by ab initio calculations at the MP2 level using the LANL2DZ basis for Ru and P, and 6-31G for the rest of atoms.

The exclusive formation of **4** starting from **3** and **1** suggests that the addition of bulky phosphines to the C_{α} atom is kinetic and thermodynamically favored over addition at the C_{γ} atom. The origin of this preference may be the steric congestion due to the phenyl groups on the C_{γ} atom.⁴ In fact, theoretical calculations at the MP2 level on the model compounds $[Ru(\eta^5-C_5H_5)-\{C(PH_3)=C=CH_2\}(CO)(PH_3)]^+$ and $[Ru(\eta^5-C_5H_5)\{C=CC-(PH_3)H_2\}(CO)(PH_3)]^+$ indicate that both isomers are minima on the potential energy surface and that the difference of energy between them is not more than 3 kcal·mol⁻¹.

In contrast to PRPh₂ (R = H, Me, Ph), the nucleophiles [OMe]⁻ and OH⁻ add at the C_{γ} atom of **1**, leading to the alkynyl complexes Ru(η^{5} -C₅H₅)(C=CC(OR)Ph₂}-(CO)(PPrⁱ₃) [**6** (R = Me), **7** (R = H)] in Scheme 2. Their formation is mainly supported by the IR and ¹³C{¹H} NMR spectra. The IR spectra show the ν (C=C) bands at 2108 (**6**) and 2119 (**7**) cm⁻¹, while the ¹³C{¹H} NMR spectra contain resonances at 107.6 and 96.5 (**6**) and 112.1 and 95.3 (**7**) ppm, corresponding to the C_{β} and C_{α} atoms of the alkynyl ligands.

Although the alkoxyallenyl complex $\text{Ru}(\eta^5\text{-}C_5\text{H}_5)$ -{ $(C(OMe)=C=CPh_2$ }(CO)(PPrⁱ₃) has been previously reported,^{8a} isomerization of **6** into this derivative is not observed. This is in agreement with theoretical calculations on the complexes $\text{Ru}(\eta^5\text{-}C_5\text{H}_5)$ { $C(OMe)=C=CH_2$ }-(CO)(PH₃) and $\text{Ru}(\eta^5\text{-}C_5\text{H}_5)$ (C=CC(OMe)H₂}(CO)(PH₃) (**a** and **b** in Figure 2), which indicate that the second model compound is 9.29 kcal·mol⁻¹ more stable than the first one.¹⁴ Furthermore, according to EHT-MO calculations,^{1d} the net charge on the C_{α} atom of [$\text{Ru}(\eta^5\text{-}C_5\text{H}_5)$ -(C=C=CH₂)(CO)(PH₃)]⁺ (-0.36) is significantly higher

than that on C_{γ} (-0.05). So, the addition of hard nucleophiles at the C_{γ} atom of **1** appears to be favored from an electronic point of view.

In conclusion, the allenylidene ligand of **1** adds bulky phosphines at the C_{α} atom, whereas hard nucleophiles such as OMe⁻ and OH⁻ add at the C_{γ} atom. The preference of the phosphine nucleophiles has its origin in the steric congestion due to the phenyl groups on the C_{γ} atom. However, the preference of the hard nucleophiles seems to be electronic and related to the smaller net charge on the C_{γ} atom.

Experimental Section

All reactions were carried out with rigorous exclusion of air using Schlenk-tube techniques. Solvents were dried by the usual procedures and distilled under argon prior to use. The starting material [Ru(η^{5} -C₅H₅)(C=C=CPh₂)(CO)(PPrⁱ₃)]BF₄ (1) was prepared by the published method.^{8a}

NMR spectra (¹H at 300 MHz, ³¹P at 121.4 MHz, and ¹³C at 75.4 MHz) were recorded at 293 K, and chemical shifts are expressed in ppm downfield from Me₄Si (¹H and ¹³C) and 85% H₃PO₄ (³¹P). Coupling constants, *J*, are given in hertz.

Preparation of $[Ru(\eta^5-C_5H_5){C(PRPh_2)=C=CPh_2}(CO)-C(PRPh_2)=C=CPh_2$ $(\mathbf{PPr^{i}_{3}})$]**BF₄** [**R** = **H** (2), **Me** (4), **Ph** (5)]. A solution of **1** (150) mg, 0.24 mmol) in 5 mL of CH_2Cl_2 was treated with PRPh₂ (0.24 mmol). Immediately, the color changed from dark red to yellow, and solvent was concentrated to ca. 1 mL. By addition of diethyl ether, a yellow solid precipitated. 2: Yield: 180 mg (93%). Anal. Calcd for C42H47BF4OP2Ru: C, 61.70; H, 5.79. Found: C, 61.56; H, 6.05. Preparation of $[Ru(\eta^5-C_5H_5){C=CC(OR)Ph_2}(CO) (\mathbf{PPr}^{i_{3}})$ [**R** = **Me** (6), **H** (7)]. A solution of **1** (130 mg, 0.20 mmol) in 5 mL of THF was treated with Na[OMe] (19 mg, 0.35 mmol) or KOH (50 mg, 85%, 0.76 mmol). The resulting suspension was stirred for 10 min or 4 h, respectively. Solvent was removed in vacuo, and the residue was extracted in 10 mL of toluene or 30 mL of hexane. The suspension was filtered, and solvent was removed in vacuo. The residue was washed with cold methanol to afford 6 or 7 as white solids. 6: Yield: 89 mg (75.1%). Anal. Calcd for C₃₁H₃₉O₂PRu: C, 64.46; H, 6.83. Found: C, 64.78; H, 6.10. IR (cm⁻¹): ν (C=C) 2108 (m), ν (CO) 1938 (vs). NMR (C₆D₆): ¹H δ 7.96 (m, 4H, o-Ph), 7.21 (m, 4H, m-Ph), 7.07 (m, 2H, p-Ph), 4.79 (s, 5H, Cp), 3.57 (s, 3H, OMe), 1.90 (m, 3H, PCHCH₃), 1.02 (dd, 9H, J(HH) = 7.1, *J*(PH) = 14.5, PCHC*H*₃), 0.78 (dd, 9H, *J*(HH) = 7.1, *J*(PH) = 13.1, PCHCH₃); ³¹P{¹H} δ 74.8 (s); ¹³C{¹H} δ 206.3 (d, J(PC) = 18.1, CO), 147.7, 147.4 (both s, C_{ipso}), 128–126.6 (Ph), 107.6 (s, C_{β}), 96.5 (d, J(PC) = 21.6, C_{α}), 85.5 (d, J(PC) = 1.8, Cp), 82.4 (s, C_{γ}), 51.6 (s, OMe), 27.2 (d, J(PC) = 23.4, $PCHCH_3$), 20.1 (s, PCHCH₃), 19.4 (d, J(PC) = 1.9, PCHCH₃). 7: Yield: 92 mg (79%). Anal. Calcd for C₃₀H₃₇O₂PRu: C, 64.15; H, 6.63. Found: C, 64.32; H, 6.99. IR (cm⁻¹): ν (OH) 3560 (m), ν (C= C) 2119 (m), ν (CO) 1941 (vs). NMR (C₆D₆): ¹H δ 7.97 (m, 4H, o-Ph), 7.20 (m, 4H, m-Ph), 7.07 (m, 2H, p-Ph), 4.79 (s, 5H, Cp), 2.59 (s, 1H, OH), 1.91 (m, 3H, PCHCH₃), 1.02 (dd, 9H, J(HH) $= 7.1, J(PH) = 14.5, PCHCH_3), 0.80 (dd, 9H, J(HH) = 7.1,$ $J(PH) = 13.1, PCHCH_3$; ³¹P{¹H} δ 74.7 (s); ¹³C{¹H} δ 206.2 (d, J(PC) = 17.4, CO), 149.2 (s, C_{ipso}), 128–126.5 (Ph), 112.1 (s, C_{β}), 95.3 (d, J(PC) = 21.1, C_{α}), 85.6 (d, J(PC) = 1.5, Cp), 75.8 (s, C_{γ}), 27.2 (d, J(PC) = 23.3, $PCHCH_3$), 20.2 (s, $PCHCH_3$), 19.4 (d, J(PC) = 2.3, $PCHCH_3$).

X-ray Structure Determination of 3. Complex **3** is triclinic, space group $P\overline{1}$, a = 10.163(4) Å, b = 12.749(4) Å, c = 15.449(6) Å, $\alpha = 98.10(2)^\circ$, $\beta = 100.62(2)^\circ$, $\gamma = 108.76(2)^\circ$, Z = 2; 9507 reflections $(\pm h, +k, \pm l)$ were collected at room temperature with a Siemens Stoe-AED2 diffractometer over a 2θ range of $3-50^\circ$. An empirical absorption correction from Ψ scans was applied to the data ($\mu = 0.55$ mm⁻¹). Structural solutions by Patterson and least-squares refinement (based on F^2) were performed with SHELXTL v. 5.0. The refinement on 5720 ($F_0^2 > 0$) data converged at $wR_2(F^2) = 0.1594$ for all data and $R_1(F) = 0.0528$ for 4246 observed data ($I > 2\sigma(I)$). More details in the Supporting Information.

⁽¹⁴⁾ Although complex **6** appears to be thermodynamically more stable than $Ru(\eta^5-C_5H_5)$ {C(OMe)=C=CPh₂}(CO)(PPr⁴₃), isomerization of the latter into **6** is not observed. This could be due to the fortness of the C_{α} -OMe bond, which imposes a high activation barrier for the isomerization.
