### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

**ABSTRACT**

Ionic liquid (IL)-based aqueous two-phase systems (ATPSs) have attracted much attention in the separation technology. In this work, we synthesized five novel ether-functionalized ILs and studied their applications in ATPS formation. The phase diagrams for several systems were determined at 298.15 K. An as-prepared IL (1-(2-butoxy-ethyl)-3-methylimidazolium chloride) was chosen as a representative to construct ATPSs for separation of bovine serum albumin (BSA) from aqueous saccharide solutions. Results showed that 76.1% – 94.3% of BSA was enriched into the IL-rich top phase and almost all the saccharides were extracted into the salt-rich bottom phase in one-step separation process. The main factors affecting the separation process, such as kinds of saccharides and the amount of inorganic salts, were discussed. Furthermore, the size distributions of aggregates in the IL-rich top phase were determined by dynamic light scattering (DLS), and accordingly the possible mechanism for the separation was investigated.

**KEYWORDS:** aqueous two-phase system; ether-functionalized ionic liquid; bovine serum albumin; saccharides; separation

## 1. INTRODUCTION

Proteins and saccharides are important components of living organism, and coexist generally together. They are separated and purified difficultly. For example, the crude saccharides often contain a large number of non-carbohydrate substances, such as proteins.<sup>1</sup> Furthermore, the existence of saccharides causes significant deviation from the actual absorbance of proteins in the Bradford protein assay.<sup>2</sup> Therefore, the separation of the complex mixtures has become a focus of the researches. Several methods have been applied in the biological sample separation: gas chromatography/mass spectrometry, liquid-liquid extraction, and solid-phase extraction.<sup>3,4</sup> As a kind of liquid-liquid extractive technique, aqueous two-phase system (ATPS) is simple, low cost, and relatively reliable in scale-up, and has a great potential in separation application. Kula and co-workers published a number of papers describing the use of ATPS for protein purification.<sup>5,6</sup> The practical application of ATPSs to process development has been exploited for the recovery of biological products.<sup>7,9</sup>

Ionic liquids (ILs) as environment-friendly and designed solvents are attracting. In 2003, for the first time, Rogers and co-workers<sup>10</sup> reported on a new ATPS composed of a hydrophilic IL, 1-butyl-3-methylimidazolium chloride ( $[C_4mim]Cl$ ), and a inorganic salt ( $K_3PO_4$ ). The inorganic salt at a high concentration increased the hydrophobicity of the bottom phase containing rich-salt.<sup>11</sup> In rich-salt phase, the solubility of protein was markedly reduced because of the competition for water molecules between the protein and inorganic ions. Consequently, the addition of

1  
2  
3  
4 inorganic salts enhances the transfer of protein from the bottom phase to the top  
5  
6 phase.<sup>12</sup> Moreover, in the process of forming ATPSs, the negatively charged amino  
7  
8 acids on the surface of protein interact with the positively charged IL-cation.<sup>13</sup> These  
9  
10 factors promote the transfer of protein to the top phase. Therefore, we can change the  
11  
12 structures of ILs and kinds of inorganic salts to improve the extraction efficiency of  
13  
14 proteins using IL-based ATPSs. Recently, IL-based ATPSs are widely used for the  
15  
16 separation and purification of various biomolecules,<sup>14,15</sup> based on their unique  
17  
18 properties such as low viscosity, quick phase separation, high extraction efficiency,  
19  
20 and gentle biocompatible environment.<sup>16,17</sup> A lot of researches were restricted to the  
21  
22 extraction of the single component from one phase to another. However, IL-ATPS for  
23  
24 separation of bovine serum albumin (BSA) from aqueous saccharide solutions was  
25  
26 rarely reported. In previous work, we reported on the separation of BSA from aqueous  
27  
28 saccharides solutions using an ATPS constructed by 1-butyl-3-methylimidazolium  
29  
30 dicyanamide [C<sub>4</sub>mim][N(CN)<sub>2</sub>], K<sub>2</sub>HPO<sub>4</sub>, and H<sub>2</sub>O.<sup>18</sup> Results showed that more than  
31  
32 82% of BSA could be enriched into the IL-rich top phase and almost all the  
33  
34 saccharides were extracted into the salt-rich bottom phase of ATPS. It is highly  
35  
36 desired to construct new IL-based ATPSs for separations.

48  
49

50 To form the IL-water biphasic systems for the extraction, hydrophobic ILs have  
51  
52 to be used. Hydrophobic ILs are more expensive than hydrophilic ILs and the number  
53  
54 of hydrophobic ILs is limited. In addition, using the simple IL-water biphasic systems  
55  
56 for separation of biomacromolecules, their denaturation would happen possibly in the  
57  
58 separation process.<sup>18</sup> Therefore, hydrophilic ILs are more likely used in the extraction  
59  
60

1  
2  
3  
4 process. In recent decades, a lot of hydrophilic ILs were synthesized and applied to  
5  
6 form ATPSs for extraction separation. For example, [C<sub>6</sub>mim]Cl was used to construct  
7  
8 ATPSs for extraction of BSA.<sup>19</sup> The ether-functionalized ILs also are hydrophilic. But  
9  
10 compared with the alkyl-substituted ILs, they have a variety of unique properties,  
11  
12 such as lower viscosity and lower melting point.<sup>20,22</sup> In addition, the ether group  
13  
14 reduces the toxicity of ILs.<sup>23</sup> Therefore, it is significant to use the  
15  
16 environment-friendly ether-based ILs for separation processes.  
17  
18  
19  
20  
21

22  
23 Herein, we synthesized five novel (except [C<sub>2</sub>OC<sub>2</sub>mim]Cl) hydrophilic  
24  
25 ether-functionalized ionic liquids: 1-(2-alkoxy-ethyl)-3-methylimidazolium chloride  
26  
27 ([C<sub>n</sub>OC<sub>2</sub>mim]Cl ( $n = 2, 3, 4$ )), 1-(2-propoxy-ethyl)-3-methylimidazolium  
28  
29 p-toluenesulfonic acid ([C<sub>3</sub>OC<sub>2</sub>mim][p-TSA]), and  
30  
31 1-(2-benzyloxy-ethyl)-3-methylimidazolium p-toluenesulfonic acid  
32  
33 ([PhCOC<sub>2</sub>mim][p-TSA]). The ability of the ether-functionalized ILs for the formation  
34  
35 of IL-based ATPSs was discussed. For such a purpose, phase diagrams for systems  
36  
37 composed of different ether-functionalized ILs, inorganic salts (K<sub>3</sub>PO<sub>4</sub>/K<sub>2</sub>HPO<sub>4</sub>), and  
38  
39 water at 298.15 K were determined. Then an as-prepared IL [C<sub>4</sub>OC<sub>2</sub>mim]Cl was used  
40  
41 to form IL-based ATPSs for separating BSA from aqueous saccharide (glucose,  
42  
43 sucrose, and dextran) solutions. Besides, dynamic light scattering (DLS) was applied  
44  
45 to determine the size distribution of aggregates in the top IL-rich phase and to explore  
46  
47 the possible mechanism for the separation of BSA.

## 59 2. EXPERIMENTAL SECTION

60

1  
2  
3  
4 **2.1 Materials.** 1-Methylimidazole (CP) was purchased from HWRK Chemical  
5  
6 Company (Beijing, China), 2-chloroethyl ethyl ether, 2-chloroethyl propyl ether, and  
7  
8 2-chloroethyl butyl ether were purchased from Tokyo Chemical Industry (TCI, Tokyo,  
9  
10 Japan), respectively. They were used without further purification. Ethylene glycol  
11  
12 propyl ether, p-toluenesulfonyl chloride, 4-dimethylaminopyridine, and 2-(benzyloxy)  
13  
14 ethanol were purchased from Aladdin Chemistry (Los Angeles, USA). Triethylamine  
15  
16 was purchased from Sinopharm Chemical Reagent Co (Shanghai, China). K<sub>3</sub>PO<sub>4</sub> from  
17  
18 TCI (Tokyo, Japan), K<sub>2</sub>HPO<sub>4</sub> from Alfa Aesar (Ward Hill, MA, USA), bovine serum  
19  
20 albumin (BSA), glucose, sucrose, and dextran (Mr~1500) from Sigma (St. Louis, MO,  
21  
22 USA) were used without further purification. Ultrapure water was used to prepare  
23  
24 solutions. All chemicals were of analytical grade.  
25

33 **2.2 Synthesis and Characterization of ILs.** 1-(2-Alkoxy-ethyl)-3-methylimidazo-  
34  
35 lium chlorides ([C<sub>n</sub>OC<sub>2</sub>mim]Cl (*n* = 2, 3, 4)) were synthesized according to the  
36  
37 procedure (Figure 1) described in the literature.<sup>24</sup> Chloroethyl alkylether was added  
38  
39 dropwise to 1-methylimidazole under stirring at 0 °C. The reaction temperature  
40  
41 increased to 80 °C. The mixture was stirred at 80 °C for 48 h, and then cooled to room  
42  
43 temperature, washed three times with ethyl acetate. The ethyl acetate in produce was  
44  
45 removed by rotary evaporation. The obtained ether-functionalized ILs products were  
46  
47 dried under reduced pressure for 48 h at 50 °C in the presence of P<sub>2</sub>O<sub>5</sub>. The chemical  
48  
49 structures of the ether-functionalized ILs were confirmed by <sup>1</sup>H NMR spectroscopy.  
50  
51 Their <sup>1</sup>H NMR spectral characteristics were shown as follows:

[C<sub>4</sub>OC<sub>2</sub>mim]Cl: <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>): δ 10.37 (*s*, 1H), 7.52 (*s*, 1H), 7.46 (*s*, 1H), 4.55-4.47 (*t*, 2H), 4.03 (*s*, 3H), 3.73-3.69 (*t*, 2H), 3.37 (*t*, 2H), 1.49 (*m*, 2H), 1.28-1.17 (*m*, 2H), 0.81 (*t*, 3H).

**Figure 1.** Synthesis process for [C<sub>n</sub>OC<sub>2</sub>mim]Cl (*n* = 2, 3, 4).

1-(2-Propoxy-ethyl)-3-methylimidazolium p-toluenesulfonic acid ([C<sub>3</sub>OC<sub>2</sub>mim][p-TSA]) and 1-(2-benzyloxy-ethyl)-3-methylimidazolium p-toluenesulfonic acid ([PhCOC<sub>2</sub>mim][p-TSA]) were synthesized according to the procedure (Figures 2 and 3) described in the literature.<sup>25,26</sup> Ethylene glycol propyl ether was added to a dichloromethane solution of p-toluenesulfonyl chloride under stirring at 0 °C. Then triethylamine addition was followed by a catalytic amount of 4-dimethylaminopyridine. After 4 h the solution was washed with ultrapure water, brine, and sodium bicarbonate. After drying with sodium sulfate, dichloromethane was removed by rotary evaporation. Then p-toluenesulfonate was reacted with 1-methylimidazole under stirring at room temperature. After 48 h the mixture was washed three times with ethyl acetate. The ethyl acetate was removed by rotary evaporation. The synthesis of ionic liquid [PhCOC<sub>2</sub>mim][p-TSA] followed the same procedure as the preparation of [C<sub>3</sub>OC<sub>2</sub>mim][p-TSA]. The obtained

ether-functionalized ILs products were dried under reduced pressure for 48 h at 50 °C in the presence of P<sub>2</sub>O<sub>5</sub>. Their <sup>1</sup>H NMR spectral characteristics were shown as follows:

[C<sub>3</sub>OC<sub>2</sub>mim][p-TSA]: <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>): δ 9.61 (*s*, 1H), 7.73 (*s*, 1H), 7.71 (*s*, 1H), 7.37 (*m*, 2H), 7.11 (*d*, 2H), 4.37-4.34 (*t*, 2H), 3.88 (*s*, 3H), 3.65-3.61 (*t*, 2H), 3.30 (*t*, 2H), 2.30 (*s*, 3H), 1.52-1.43 (*m*, 2H), 0.80 (*t*, 3H).

[PhCOC<sub>2</sub>mim][p-TSA]: <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>): δ 9.69 (*s*, 1H), 7.76 (*s*, 1H), 7.74 (*s*, 1H), 7.32-7.25 (*m*, 5H), 7.22-7.19 (*m*, 2H), 7.11 (*d*, 2H), 4.47-4.39 (*m*, 4H), 3.90 (*s*, 3H), 3.74 (*t*, 2H), 2.31 (*s*, 3H).

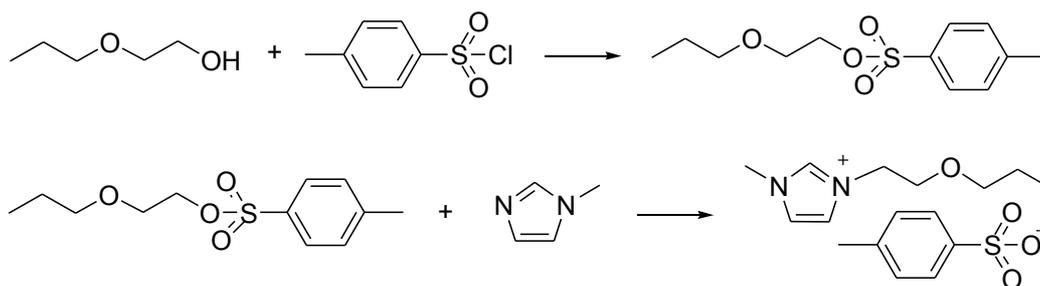

Figure 2. Synthesis process for [C<sub>3</sub>OC<sub>2</sub>mim][p-TSA].

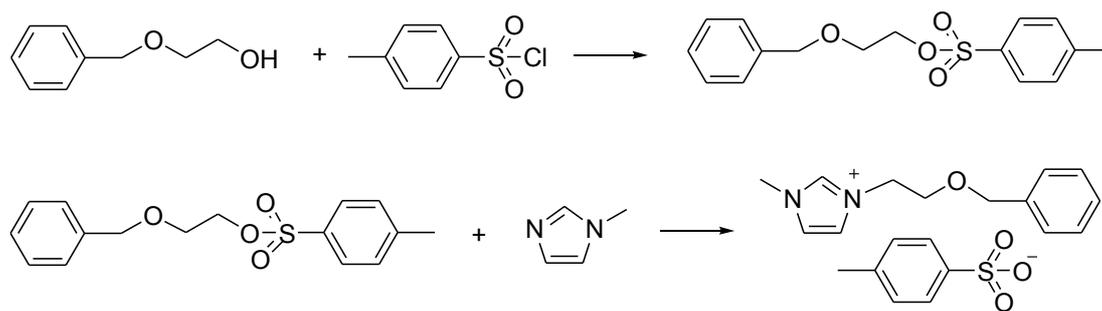

Figure 3. Synthesis process for [PhCOC<sub>2</sub>mim][p-TSA].

At the same time, based on the graphs of thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC), the thermal decomposition temperature and glass transition temperature were obtained, and are given in Table 1. Both

measurements were carried out under N<sub>2</sub> with a temperature ramp of 10 K/min.

**Table 1.** Melting Point ( $T_m$ ) and Thermal Decomposition Temperature ( $T_d$ ) of ILs.

<sup>a</sup> glass transition temperature

**2.3 Preparation of Phase Diagrams.** The phase diagrams were determined by the turbid titration method.<sup>10,18</sup> In short, a few grams of ether-based IL were weighed into a test tube. Then a small amount of water was added to the tube for dissolving the IL. A known-concentration solution of salt was added dropwise to the test tube until the mixture became turbid. The added volume of the salt solution was recorded and the composition of this mixture was calculated. Then a few drops of water was added to make the two-phase system clear again. The above procedure was repeated to gain enough data for constructing a liquid-liquid equilibrium binodal curve. The concentration of the phase components was determined by weight quantification of all the components with a standard uncertainty of 10<sup>-4</sup> g. The tie lines, which depict the concentrations of IL and salt in the top/bottom phases, were determined with the process outlined in our previous work.<sup>27</sup>

**2.4 Separation of Protein from Saccharides.** Method for the separation of protein

from saccharides is similar to our previous work.<sup>18,28</sup> The details are given in the Supporting Information. The dynamic light scattering (DLS) measurements were carried out using Zeta-Meter (Nano-ZS 90) laser light scattering photometer (Malvern, U.K.).<sup>18</sup> Also see the Supporting Information.

### 3. RESULTS AND DISCUSSION

**3.1 Phase Diagram of IL-Based ATPS.** The binodal curves and tie lines for the ether-functionalized IL + salt systems were determined at 298.15 K, and shown in Figures 4–6 and Figures S1–S3 in the Supporting Information, respectively.

The binodal data were correlated by the following equation:<sup>29</sup>

$$w_1 = a \ln(w_2 + c) + b \quad (3)$$

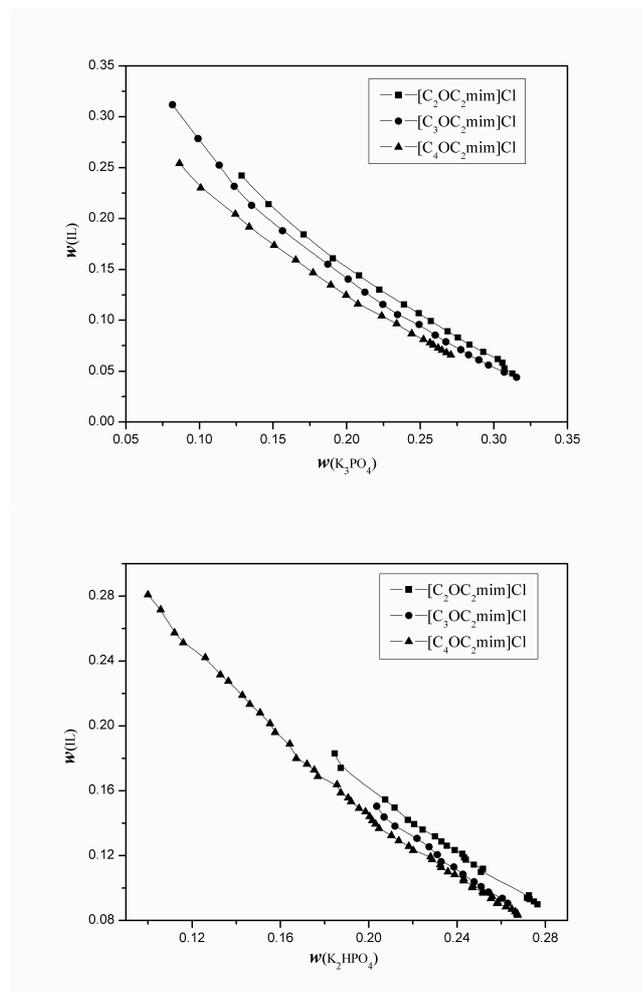

where  $w_1$  and  $w_2$  are the mass fractions of ILs and salts, respectively, and  $a$ ,  $b$ , and  $c$ , are fitting parameters. The fitting parameters gained from the correlation of experimental binodal data are given in Table 2, along with the correlation coefficients ( $R^2$ ) and the corresponding standard deviations ( $s$ ) of eq 3. Based on the obtained  $R^2$  and  $s$ , we can conclude that eq 3 has more satisfactory accuracy in binodal data fitting for the studied systems.<sup>29</sup>

**Table 2.** Parameters ( $a$ ,  $b$ , and  $c$ ) Obtained by the Regression of the Experimental Binodal Data Through the Application of Eq 3 for the IL(1) + Salt(2) + H<sub>2</sub>O Systems at 298.15 K.

3.1.1 *Effect of the structure of ILs.* ILs composed of different cations and anions have different hydrophobicity. ATPSs can be constructed by adding a certain amount of K<sub>2</sub>HPO<sub>4</sub> or K<sub>3</sub>PO<sub>4</sub> to aqueous IL solutions. Figure 4 indicates the influence of the alkyl-chain length of ILs on the phase diagrams. Obviously, the phase-forming ability of these ILs is observed: [C<sub>4</sub>OC<sub>2</sub>mim]Cl > [C<sub>3</sub>OC<sub>2</sub>mim]Cl > [C<sub>2</sub>OC<sub>2</sub>mim]Cl. This order is in agreement with chaotropic ability of IL-cations. The difference in chaotropic ability results from the structural difference of the cations.<sup>30</sup> With the increase of the alkyl-chain length ([C<sub>n</sub>OC<sub>2</sub>mim]<sup>+</sup> (*n* = 2, 3, 4)), the binodal curves are more closer to the origin,<sup>31</sup> showing that the phase-forming ability of ILs increases with increasing alkyl-chain length. That is to say, [C<sub>4</sub>OC<sub>2</sub>mim]Cl is the most chaotropic salt and this binodal is furthest to the left (it is the easiest to salt-out). Obviously, the phase-forming ability of [C<sub>4</sub>OC<sub>2</sub>mim]Cl is the best among the three ILs.

**Figure 4.** Phase diagrams for the aqueous two-phase systems composed by  $[\text{C}_2\text{OC}_2\text{mim}]\text{Cl}$  /  $[\text{C}_3\text{OC}_2\text{mim}]\text{Cl}$  /  $[\text{C}_4\text{OC}_2\text{mim}]\text{Cl}$  +  $\text{K}_3\text{PO}_4$  /  $\text{K}_2\text{HPO}_4$  at 298.15 K:  $w$ , mass fraction.

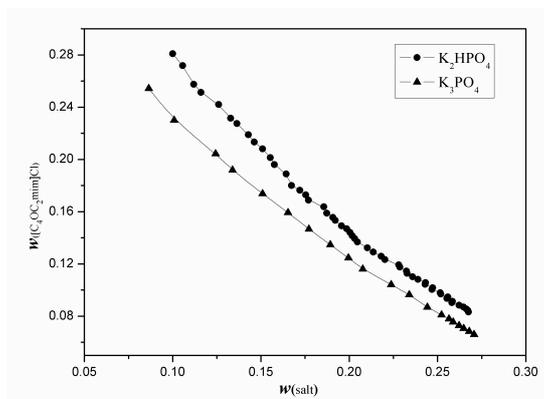

Figure 5 indicates the effect of ions of ether-based ILs on the phase diagram. At a certain amount of  $\text{K}_3\text{PO}_4$ , the phase-forming ability of these ILs is observed:  $[\text{PhCOC}_2\text{mim}][\text{p-TSA}] > [\text{C}_3\text{OC}_2\text{mim}][\text{p-TSA}] > [\text{C}_3\text{OC}_2\text{mim}]\text{Cl}$ . This can be interpreted by the facts that the addition of the electro-rich aromatic  $\pi$  system (hydrophobic) to the cation and anion increases the hydrophobicity of the IL,<sup>32,33</sup> and then increase the phase-forming ability. Therefore, we suggest that the hydrophobicity of the ILs play a critical role in aqueous two-phase extraction process.

**Figure 5.** Phase diagrams for the aqueous two-phase systems composed by [PhCOC<sub>2</sub>mim][p-TSA] / [C<sub>3</sub>OC<sub>2</sub>mim][p-TSA] / [C<sub>3</sub>OC<sub>2</sub>mim]Cl + K<sub>3</sub>PO<sub>4</sub> at 298.15 K: *w*, mass fraction.

*3.1.2 Effect of salt category.* Figure 6 shows the phase diagrams for the ATPSs of [C<sub>4</sub>OC<sub>2</sub>mim]Cl with K<sub>2</sub>HPO<sub>4</sub>/K<sub>3</sub>PO<sub>4</sub>. It can be seen that the binodal curve for K<sub>3</sub>PO<sub>4</sub> is closer to the origin than that for K<sub>2</sub>HPO<sub>4</sub>. Consequently, the phase-forming ability of both salts is: K<sub>3</sub>PO<sub>4</sub> > K<sub>2</sub>HPO<sub>4</sub>. This order is the same as the previous researches on the ATPSs of [C<sub>4</sub>mim]X (X=Cl or Br) and [C<sub>*n*</sub>mim]Br (*n* = 6 or 8).<sup>30,34</sup> Since cation of both salts is the same K<sup>+</sup>, but anions are different, the phase-forming ability is controlled by different anions. Results showed that anion with higher valence was used for constructing ATPSs, a lower concentration of salt was needed. It may be explained by their different salting-out abilities (kosmotropicity): the higher valent anions show bigger salting-out ability, because the anions with high charge density can hydrate more water molecules, and thus the less water is available to hydrate ILs. This is identical to the hydration Gibbs free energy of the anions: HPO<sub>4</sub><sup>2-</sup> (−1125 kJ·mol<sup>−1</sup>), PO<sub>4</sub><sup>3-</sup> (−2765 kJ·mol<sup>−1</sup>).<sup>35</sup> The order is also in agreement with the strength of the kosmotropic salts (Hofmeister series). Since K<sub>2</sub>HPO<sub>4</sub> is able to make a suitable

pH range for the gentle separation of BSA, it was selected for the further researches in the present work.

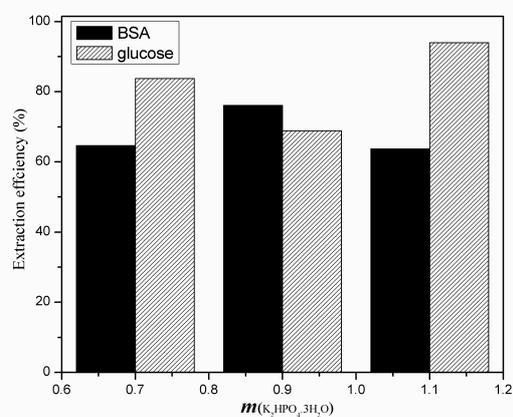

**Figure 6.** Phase diagrams for the aqueous two-phase systems composed by  $[\text{C}_4\text{OC}_2\text{mim}]\text{Cl} + \text{K}_3\text{PO}_4 / \text{K}_2\text{HPO}_4$  at 298.15 K:  $w$ , mass fraction.

### 3.2 Separation of BSA and Saccharides in $[\text{C}_4\text{OC}_2\text{mim}]\text{Cl} + \text{K}_2\text{HPO}_4$ ATPSs

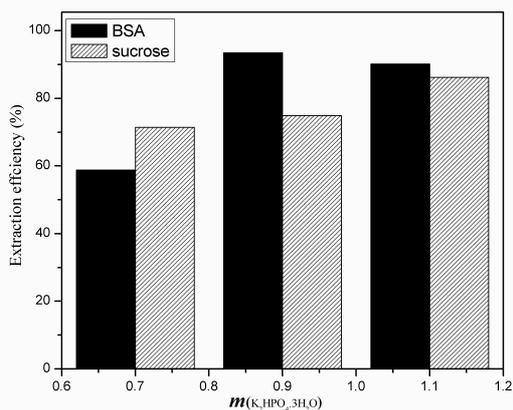

*3.2.1 Effect of inorganic salt amount.* Amount of salts is a key factor to control the extraction efficiency.<sup>36</sup> As shown in Figure 7, as the concentration of salts ( $\text{K}_2\text{HPO}_4$ ) increases, the extraction yield for BSA increases at first and decreases afterwards. The possible reason is that  $\text{K}_2\text{HPO}_4$  has a strong salting-out effect.<sup>37</sup> When kosmotropic ions were added into aqueous solutions of ILs, the molecules of water surrounding the ions would become electro-constriction states. Hence, the hydrogen bonding of water was increased in the phase, and thus more energy is required to form a cavity in this solution for the organic cation  $[\text{C}_4\text{OC}_2\text{mim}]^+$ .<sup>10</sup> As the concentration of salt increases, the salt-rich bottom phase became more hydrophobic<sup>38</sup> and more structured, and consequently the solubility of protein was markedly reduced because of the competition for water molecules between the protein molecules and inorganic ions.<sup>12</sup>

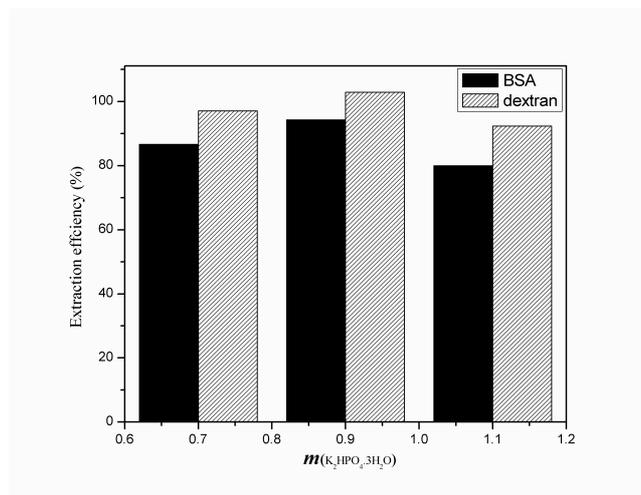

Moreover, in the process of forming ATPSs, the negatively charged amino acids on the surface of protein interact with the positively charged IL-cation.<sup>13</sup> These factors lead to a larger transfer of protein to the top IL-rich phase. At a given content of inorganic salt, the ILs with the more hydrophobic cations and the less water-structuring anions would be separated from the inorganic salts. However, extraction efficiency decreases when the content of inorganic salt is too high. The possible reason is the denaturation of protein to some extent under the circumstance.

Furthermore, these  
from water solution  
extraction of biom

ch hydrophilic ILs  
appropriate for the

**Figure 7.** Effect of the concentration of salt on the extraction efficiency of BSA and saccharides in  $[\text{C}_4\text{OC}_2\text{mim}]\text{Cl} + \text{K}_2\text{HPO}_4 \cdot 3\text{H}_2\text{O}$  ATPSs at 298.15 K: the concentrations of BSA and saccharides were at  $4.0 \text{ mg} \cdot \text{mL}^{-1}$  and  $1.0 \text{ mg} \cdot \text{mL}^{-1}$ , respectively; 0.4 g IL, 1.2 mL  $\text{H}_2\text{O}$  were added for the construction of ATPSs;  $m$  (g) is the total mass of  $\text{K}_2\text{HPO}_4 \cdot 3\text{H}_2\text{O}$  added. The deviations of extraction efficiency of BSA and saccharides were 2% and 5%, respectively.

*3.2.2 Effect of different saccharides.* Table 3 shows that the extraction yields of different saccharides and BSA in  $[\text{C}_4\text{OC}_2\text{mim}]\text{Cl} + \text{K}_2\text{HPO}_4$  ATPSs. From this table, we observed that the extraction yields for BSA from the saccharide solutions increase with the increase of the number of hydroxyl groups in a saccharide molecule (dextran > sucrose > glucose). The extraction yields of BSA from different saccharide solutions are different. Most of the sugars were separated into the salt-rich phase. Because of the positive values of viscosity  $B$  coefficients of saccharides in aqueous solutions, the saccharide molecules act overall as kosmotropes (to form stronger hydrogen bond networks with water).<sup>39,41,42</sup> Moreover, the greater the number of hydroxyl groups on a sugar molecule, the more kosmotropic the sugar. Therefore, the presence of sugar in the  $[\text{C}_4\text{OC}_2\text{mim}]\text{Cl} + \text{K}_2\text{HPO}_4$  ATPS would be benefited to the

1  
2  
3  
4 separation of kosmotropic salt  $K_2HPO_4$ . Because of the formation of hydrogen bonds  
5  
6 between water and saccharide molecules, the content of free water in the bottom  
7  
8 salt-rich phase will decrease, which forces more chaotropic IL and BSA to be  
9  
10 transferred into the top IL-rich phase, compared with the ATPSs without saccharides.  
11  
12  
13 Consequently, the number of hydroxyl groups on saccharide molecules is a key factor  
14  
15 influencing the distribution of saccharides and BSA in these ATPSs.  
16  
17  
18

19  
20 Experimental results showed that 76.1% – 94.3% of the BSA were extracted into  
21  
22 the top IL-rich phase and sugars were separated into the bottom salt-rich phase in  
23  
24 one-step separation process. Compared with our previous work,<sup>18</sup> the ATPSs based on  
25  
26 ether-functionalized ILs also exhibit excellent extraction efficiency for BSA from  
27  
28 aqueous saccharides. Furthermore, the ether-based ILs possess low viscosity, low  
29  
30 melting point, and low toxicity, and thus have wide application in the extraction  
31  
32 separation by using IL-based ATPSs.  
33  
34  
35

3  
4 **3.3 Size Distribution of Aggregates.** In order to understand the separation process,  
5  
6  
7 we measured the size distribution of aggregates in the IL-ATPSs. In the  
8  
9  
10  $[C_4OC_2mim]Cl + K_2HPO_4$  ATPS, the IL-rich top phase consists of IL, less amount of  
11  
12 inorganic salt, and water, and the salt-rich bottom phase consists of inorganic salt, less  
13  
14 amount of IL, and water. In the top IL-rich phase, the presence of high IL  
15  
16 concentration causes a remarkable aggregation of cations of the IL due to their  
17  
18 amphiphilic characteristics.<sup>43</sup> To confirm the state of  $[C_4OC_2mim]Cl$  in the IL-rich  
19  
20 phase, we measured the size distribution of aggregates for  $[C_4OC_2mim]Cl$  and BSA in  
21  
22 the aqueous solution by DLS at 298.15 K, and the results are shown in Figure 8.

Obviously, when BSA was added to the ATPS, a novel aggregate was generated at 260 nm. The novel aggregate is larger than both BSA and IL aggregates. The similar results were observed. We could conclude that the separation of novel IL-protein complex aggregates.

**Figure 8.** Size distribution of the aggregates of BSA, IL, and BSA + IL in aqueous solution: (a) BSA ( $1.23 \text{ g}\cdot\text{L}^{-1}$ ); (b) IL ( $1.2 \text{ mol}\cdot\text{kg}^{-1}$ ); (c) BSA ( $1.23 \text{ g}\cdot\text{L}^{-1}$ ) + IL ( $1.2 \text{ mol}\cdot\text{kg}^{-1}$ ).

#### 4. CONCLUSIONS

In this work, we synthesized five novel hydrophilic ether-functionalized ionic liquids and studied their applications in ATPS formation. The phase diagrams for several systems were determined at 298.15 K. The results showed that BSA was extracted into the IL-rich top phase but most of saccharides were transferred into the salt-rich bottom phase. Extraction yield of BSA enhanced with increasing the number of hydroxyl groups in a saccharide molecule (dextran > sucrose > glucose). The generation of the novel IL-protein complex aggregates is a key factor for separation of BSA from the aqueous solutions of saccharides. We expect that  $[\text{C}_4\text{OC}_2\text{mim}]\text{Cl} +$

1  
2  
3  
4  $K_2HPO_4$  ATPSs have a potential to separate protein from saccharide solutions, and  
5  
6  
7 therefore highlight a new opportunity of ether-functionalized IL-ATPSs to separate  
8  
9  
10 biomolecules from complex systems.
