#### Abstract

A class of zinc reagents $\left(\mathrm{RXZnCH} \mathrm{Z}_{2} \mathrm{Y}\right)$ generated with an appropriate organozinc is very effective for the cyclopropanation of olefins. The reactivity and selectivity of these reagents can be regulated by tuning the electronic and steric nature of the $R X$ group on Zn . A reasonable level of enantioselectivity was obtained for the cyclopropanation of unfunctionalized olefins when a chiral (iodomethyl)zinc species was used, providing a valuable approach for the asymmetric cyclopropanation of unfunctionalized olefins.

The Simmons-Smith reaction is a very powerful method for the cyclopropanation of olefins, ${ }^{1}$ and various versions of this reaction have been developed. In Simmons and Smith's original studies, the cyclopropanation reagent $\mathrm{I} \mathrm{ZnCH}_{2} \mathrm{l}$ was generated from $\mathrm{CH}_{2} \mathrm{I}_{2}$ and $\mathrm{Zn}-\mathrm{Cu} .{ }^{2,3}$ This $\mathrm{CH}_{2} \mathrm{I}_{2}-\mathrm{Zn}$ procedure with various modifications ${ }^{4}$ has been widely used since then. ${ }^{1}$ Wittig showed that cyclopropanation reagents $\mathrm{XZnCH}_{2} \mathrm{X}$ or $\mathrm{Zn}\left(\mathrm{CH}_{2} \mathrm{X}\right)_{2}$ could also be prepared by reacting $\mathrm{ZnX} \mathrm{X}_{2}$ with $\mathrm{CH}_{2} \mathrm{~N}_{2} .{ }^{5}$ In 1966, Furukawa reported that cyclopropanation reagents could be generated by the alkyl exchange between $\mathrm{Et}_{2} \mathrm{Zn}$ and $\mathrm{CH}_{2} \mathrm{I}_{2},{ }^{6,7}$ giving active species EtZnCH 2 or $\mathrm{Zn}\left(\mathrm{CH}_{2} \mathrm{I}\right)_{2}$. In another study, Denmark found that the (chloromethyl)zinc reagent generated from

[^0]$\mathrm{Et}_{2} \mathrm{Zn}$ and $\mathrm{ClCH}_{2} \mathrm{I}$ is more reactive than the corresponding (iodomethyl)zinc from $\mathrm{Et}_{2} \mathrm{Zn}$ and $\mathrm{CH}_{2} \mathrm{I}_{2} .{ }^{8}$ Recently, Charette has reported that bipy• $\mathrm{Zn}\left(\mathrm{CH}_{2} \mathrm{I}\right)_{2}$ complex can be isolated and stored for an extended period of time in the freezer with little decomposition. ${ }^{9}$ This complex can effectively cyclopropanate ol efins upon addition of $\mathrm{ZnI}_{2}$. In addition to (halomethyl)zinc reagents, (acyloxymethyl)zinc species can also cyclopropanate olefins. Wittig reported that bis(benzoyloxymethyl)zinc [(PhCOOCH $\left.)_{2}\right)_{2-}$ Zn ] could cyclopropanate olefins upon activation by $\mathrm{ZnI}_{2 .}{ }^{5 \mathrm{~d}}$ Very recently, Charette has shown that $\mathrm{n}-\mathrm{C}_{4} \mathrm{~F}_{9}{ }^{-}$ $\mathrm{COOCH}_{2} \mathrm{ZnEt}$ generated from $\mathrm{n}-\mathrm{C}_{4} \mathrm{~F}_{9} \mathrm{COOCH}_{2} \mathrm{l}$ and $\mathrm{Et}_{2} \mathrm{Zn}$ is a highly reactive cyclopropanating reagent. ${ }^{10}$ Significant progress has also been made in the structural elucidation of various possible reactive cyclopropanating species. Several (halomethyl)zinc compounds or their complexes with other ligands have been investigated and characterized via both X-ray crystallography and NMR spectroscopy by Denmark ${ }^{11}$ and Charette. ${ }^{7 b, 9,12}$

As mentioned above, a (halomethyl)zinc reagent in the Simmons-Smith reaction is generally represented as $\mathrm{XZnCH}_{2} \mathrm{Y}(\mathbf{1})^{13}$ where the X substituent on the Zn is usually limited to halogens, $\mathrm{Et}, \mathrm{YCH}_{2}$, or other alkyl groups ${ }^{14}$ depending upon the protocol used (Scheme 1). In 1998, we reported that the cyclopropanation of ol efins can be efficiently carried out using a new class of (iodomethyl)zinc species ( $\mathrm{RXZnCH} \mathrm{Z}_{2} \mathrm{I}$ ) generated by reacting RXH with an appropriate organozinc reagent (Scheme 2). ${ }^{15} \mathrm{~A}$ wide range of RXH from alcohols to acids can be

[^1]
## SCHEME 1

SCHEME 2

used to form the (iodomethyl)zinc species, ${ }^{15,16}$ and the reactivity of these resulting cyclopropanation reagents can be regulated by changing the electronic and/or steric nature of the modifier RXH. Furthermore, we showed that the asymmetric cydopropanation of unfunctionalized olefins is possible with a chiral RXH. ${ }^{15}$ Herein we wish to report our detailed studies on this subject.

## Results and Discussions

We began our studies by generating a series of (iodomethyl)zinc species from various modifiers and studying their reactivity. A number of methods are concei vable for the generation of $\mathrm{RXZnCH} \mathrm{Z}_{2}$ (3) from RXH as shown in Scheme 3. ${ }^{17}$ In Method $\mathrm{A}, \mathrm{Et}_{2} \mathrm{Zn}$ is treated with 2 equiv of $\mathrm{CH}_{2} \mathrm{I}_{2}$ to form $\mathrm{Zn}\left(\mathrm{CH}_{2} \mathrm{I}\right)_{2}$, which subsequently reacts with RXH (2) to generate RXZnCH 2 (3). In Method B, $E t_{2} Z n$ is combined with RXH first to form RXZnEt, which then reacts with 1 equiv $\mathrm{CH}_{2} \mathrm{I}_{2}$ to generate $\mathrm{RXZnCH} \mathrm{I}_{2}$. In method $\mathrm{C}, \mathrm{Et}_{2} \mathrm{Zn}$ reacts with 1 equiv of $\mathrm{CH}_{2} \mathrm{I}_{2}$ to form EtZnCH 2 I (4), which is then treated with RXH to generate $\mathrm{RXZnCH} \mathrm{Z}_{2}$ (it should be pointed out that the various iodomethylzinc species in Scheme 3 are currently proposed only on the basis of stoichiometry). Methods B and $C$ require 1 equiv of $\mathrm{CH}_{2} \mathrm{I}_{2}$ less than Method $A$.

For our initial studies, Method A was used to generate $\mathrm{RXZnCH} 2 l$ and trans- $\beta$-methylstyrene was used as the substrate. As shown in Figure 1, the reactivity of $\mathrm{RXZnCH} \mathrm{Z}_{2}$ was highly dependent upon the RX group. When RXH was EtOH or $\mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{OH}$, no reaction occurred after stirring for 24 h at room temperature. ${ }^{18,19}$ It was found that, in general, as RXH became more

[^2]acidic, the reactivity increased. While no cycl opropanation was observed with phenol, ${ }^{20}$ cyclopropanation occurred when certain substituted phenols were used (Figure 1). ${ }^{16} \mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$ was found to accelerate the cyclopropanation reaction dramatically compared to the standard cyclopropanation conditions (i.e., without RXH). The reaction was complete within 30 min at room temperature for trans- $\beta$-methylstyrene and was very clean as judged by the ${ }^{1} \mathrm{H}$ NMR of the crude reaction mixture. To further compare the cyclopropanation reactivities, the Zn reagents generated from a variety of RXH modifiers were tested with trans- $\beta$-methylstyrene and trans-stilbene. ${ }^{21,22}$ The reagents generated from halo-gen-substituted carboxylic acids such as $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$ and $\mathrm{CCl}_{3} \mathrm{CO}_{2} \mathrm{H}$ were found to be among the most reactive cyclopropanation reagents (Table 1, entries 5, 6, 11, and 12). The reactivity of the generated Zn reagent is also affected by the solubility and stability of the reagent. For example, the relatively poor conversion observed with $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{ZnCH}_{2}$ ( Table 1, entry 2) could be due to its poor solubility in the noncoordinating solvents required for this reaction and/or its instability.

The induction periods displayed in the cases of $\mathrm{Cl}_{2} \mathrm{CHCH}_{2} \mathrm{OH}$ and $\mathrm{Cl}_{3} \mathrm{CCH}_{2} \mathrm{OH}$ (curves C and D, Figure 1) suggested that the cyclopropanation might be accelerated by the reaction products, possibly ROZnI. ${ }^{23}$ In light of this observation, the effects of Lewis acids on the cyclopropanation of unreactive $\mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{OZnCH}_{2}$ (curve B, Figure 1) were investigated. ${ }^{24-27}$ It was found that cyclopropanations proceeded at a reasonable rate when the proper Lewis acid was used (Table 2). Among these Lewis acids, $\mathrm{TiCl}_{4}, \mathrm{SnCl}_{4}, \mathrm{AICl}_{3}, \mathrm{AIEt}_{3}$, and $\mathrm{Et}_{2} \mathrm{AICl}$ were the best activators. The Lewis acid may accelerate the cyclopropanation in a number of ways. ${ }^{25-27}$ One of these is that the Lewis acid may disrupt the aggregate of ROZnCH $2 l$ by complexing to the oxygens (Scheme 4) and generate a vacant orbital on zinc for iodine to coordinate,

${ }^{\text {a }} \mathrm{RXZnCH} \mathrm{H}_{2}$ was generated by treating $\mathrm{Zn}\left(\mathrm{CH}_{2} \mathrm{l}\right)_{2}$ with $\mathrm{RXH}(1: 1)$ (Method A$)$, and all reactions were carried out with a 2:1 ratio of $\mathrm{Zn} / 0$ efin in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature. The conversion was determined by GC. ${ }^{\text {b }}$ Performed with 0.5 equiv of RXH relative to $\mathrm{Zn}\left(\mathrm{CH}_{2} \mathrm{I}\right)_{2}$.
thus activating the methylene group toward cyclopropanation. ${ }^{28}$ The complexation of the Lewis acid to the oxygen could also increase the electrophilicity of the methylene group, further accelerating the cyclopropanation.

The high reactivity displayed by $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{I}$ prompted us to examine more substrates to test its scope.

[^4]As shown in Table 3, a variety of substrates can be converted into cyclopropanes efficiently by this reagent within a short period of time. Having these cyclopropanation reactions proceed with high conversion is operationally beneficial since it is often difficult to separate the starting olefin from the cyclopropane. Considering that many cyclopropanation protocols require refluxing and long reaction times, $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{l}$ and related

${ }^{\text {a }}$ All reactions were carried out with a 2:1 ratio of Zn /olefin and 0.3 equiv of Lewis acid in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature. ${ }^{b}$ Conversion was determined from the crude reaction mixture by GC.

FIGURE 1. Plot of the conversion of trans- $\beta$-methylstyrene against time (h). The curves presented are: (A) no RXH, (B) EtOH (similar results obtained with $\mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ ), (C) $\mathrm{Cl}_{2} \mathrm{CHCH}_{2} \mathrm{OH}$, (D) $\mathrm{CCl}_{3} \mathrm{CH}_{2} \mathrm{OH}$, (E) $\mathrm{CF}_{3} \mathrm{CH}_{2} \mathrm{OH}$, (F) 2-chlorophenol, (G) 2,6-dichlorophenol, (H) $\mathrm{PhCO}_{2} \mathrm{H}$, and (I) $\mathrm{CF}_{3-}$ $\mathrm{CO}_{2} \mathrm{H}$. The RXZnCH ${ }_{2}$ l was generated by Method A. All reactions were carried out with a $2: 1$ ratio of Zn /olefin in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature.
reagents should provide an attractive alternative, particularly for substrates that are slow to react by other methods. ${ }^{29}$ It should be pointed out that better yields are usually obtained if the reaction is stopped as soon as the starting material is consumed since unnecessarily long reaction times could lead to the decomposition of the cyclopropane product. ${ }^{30}$

## SCHEME 4

## SCHEME 5

$$
\mathrm{Y}=\mathrm{OMe}, \mathrm{O}_{2} \mathrm{CCH}_{3}, \mathrm{O}_{2} \mathrm{CPh}, \mathrm{OTs}
$$

In addition to $\mathrm{CH}_{2} \mathrm{I}_{2}$, other $\mathrm{CH}_{2}$ sources such as $I \mathrm{CH}_{2} \mathrm{Cl}, \quad I \mathrm{CH}_{2} \mathrm{OMe}, \quad I \mathrm{CH}_{2} \mathrm{O}_{2} \mathrm{CCH}_{3}, \quad I \mathrm{ICH}_{2} \mathrm{O}_{2} \mathrm{CPh}$, and $1 \mathrm{CH}_{2} \mathrm{OT}$ s were also briefly investigated (Scheme 5). ${ }^{31-33}$ While $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{Cl}$ generated from $\mathrm{ICH}_{2} \mathrm{Cl}$ showed reactivities similar to $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{I}, \mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2}-$ OMe showed poor reactivity. When cyclohexene was treated with $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{OMe}$, only trace amounts of cyclopropane were observed in the crude ${ }^{1} \mathrm{H}$ NMR spectrum after extended reaction times. On the other hand, $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{O}_{2} \mathrm{CCH}_{3}, \mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{O}_{2} \mathrm{CPh}$, and $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{OTs}$ were found to be active for cyclopropanation, although their reactivities were substantially lower than $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2}$ I. For example, $90 \%$ conversion was obtained for the cyclopropanation of cyclohexene with $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2} \mathrm{O}_{2} \mathrm{CPh}$ at room temperature for 24 h . Interestingly, no cyclopropanation of cyclohexene was observed with $\mathrm{Et}_{2} \mathrm{Zn}$ and $\mathrm{ICH}_{2} \mathrm{O}_{2} \mathrm{CPh}$, suggesting that the $\mathrm{CF}_{3} \mathrm{CO}_{2}$ group greatly enhances the reactivity of the Zn reagent.

Cyclopropanation using metal carbenoids can proceed via [2 +2 ] carbometalation (pathway a) or concerted [2 $+1]$ methylene transfer (pathway b) (Scheme 6). ${ }^{1}$ The preference of the reaction pathway is highly dependent on the nature of the metal. While both pathways may compete in the cyclopropanation with lithium carbenoids, ${ }^{34}$ both experimental ${ }^{35}$ and theoretical ${ }^{36}$ studies

${ }^{\text {a }} \mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2}$ I was generated by Method $B$ except for entry 13, where Method A was used. All reactions were carried out at room temperature with 2 equiv of $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2}$ l unless otherwise noted. For entry 14, 3 equiv of $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2}$ l was used. For entries 4, 7, 13, and 16, 4 equiv of $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{ZnCH}_{2}$ l was used. ${ }^{\text {b }}$ Conversion was determined from the crude reaction mixture
 trans-cyclopropanes, and cis-olefins gave cis-cyclopropanes. e Re action was carried out at $0^{\circ} \mathrm{C}$. ${ }^{\mathrm{f}}$ Reaction was carried out at $0^{\circ} \mathrm{C}$ for 1 h and then at room temperature for $2 \mathrm{~h} .{ }^{9}$ Reaction was carried out at $0{ }^{\circ} \mathrm{C}$ for 1 h and then at room temperature for 1 h . ${ }^{\mathrm{h}}$ Yield was for the product after desilylation by TBAF.
show that cyclopropanation using zinc carbenoids proceeds by the [2 + 1] pathway, primarily due to the fact that the $\mathrm{C}-\mathrm{Zn}$ bond is covalent and unpolarized. ${ }^{36 \mathrm{~b}}$ The

[^5]
## SCHEME 6

drastic difference in reactivity observed between the traditional zinc carbenoids and the $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$-modified carbenoid prompted us to probe the mechanism of cyclopropanation using trans-1,6-diiodo-3-hexene (6) (Scheme 7). ${ }^{37}$ Cyclopropanation via the [ $\left.2+2\right]$ pathway would form both compounds 8 and 9 , while the [2+1] pathway leads to 8 exclusively. Subjecting olefin 6 to $\mathrm{CF}_{3} \mathrm{CO}_{2}{ }^{-}$ $\mathrm{ZnCH}_{2} \mathrm{l}$ at room temperature led to the clean formation of the symmetrical cyclopropane 8 as judged by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR analysis of the crude reaction mixture. This suggests that the modified zinc carbenoid behaves in a manner similar to the typical Simmons-Smith carbenoid by addition in a concerted [2 +1] fashion. However, full understanding of the reaction pathways requires further studies.

The discovery that zinc reagents modified by a covalent ligand ( $\mathrm{RXZnCH} \mathrm{Z}_{2}$ ) are effective for cyclopropanation prompted us to investigate whether a chiral (iodomethyl)zinc species ( $\mathrm{R}^{*} \times \mathrm{ZnCH}_{2} \mathrm{l}$ ) could induce enantioselectivity. Thus, a number of chiral al cohols were tested using trans-$\beta$-methylstyrene as a substrate. Generally, cyclopropanations with these $\mathrm{R} * \mathrm{OZnCH}_{2}$ l reagents were very sluggish but accelerated by the addition of a catalytic amount of Lewis acid. As shown in Table 4, $51 \%$ ee was obtained for the cyclopropane product using the fructosederived alcohol 15 as a modifier.

Great progress has been made in the area of asymmetric Simmons-Smith reactions. Efficient asymmetric cyclopropanations using a variety of chiral auxiliaries have been reported. ${ }^{38-41}$ Recently, highly enantioselective cyclopropanations of allylic al cohols have been achieved using either chiral reagents or catalysts. ${ }^{42,43}$ On the other hand, the direct asymmetric cyclopropanation of unfunctionalized olefins by transferring a methylene group from a (halomethyl)zinc reagent is an unsolved problem. Prior

${ }^{a} \mathrm{R} * \mathrm{OZnCH}_{2}$ l was generated by Method A , and all reactions were carried out with olefin ( 0.5 mmol ), $\mathrm{R} * \mathrm{OZnCH}_{2} \mathrm{l}$ ( 1.0 mmol ), and Lewis acid ( 0.15 mmol ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$-hexane at room temperature. ${ }^{\text {b }}$ Conversion was determined from the crude reaction mixture by GC. ${ }^{\text {c }}$ Enantioselectivity was determined by chiral GC (Chiraldex GTA). ${ }^{\text {d }}$ Opposite configuration was obtained.
to our earlier studies, ${ }^{15}$ only two reports appeared in the literature for asymmetric cyclopropanation of unfunctional ized ol efins using (hal omethyl) zinc reagents. In one case, (-)-menthol was used as a chiral inducer, and $<4 \%$ ee was obtained for a number of test substrates. ${ }^{4 a \mathrm{a}}$ In the other case, l-leucine was used as the chiral inducer, and an optical rotation of -0.77 was reported for cis-1-ethoxy-

[^7]2-isopropylethylene (no ee was mentioned). ${ }^{44 \mathrm{~b}}$ Although only moderate ee has been obtained, the current study provides a valuable approach toward asymmetric cyclopropanation of unfunctionalized olefins. Also, since the cyclopropanation of $\mathrm{RXZnCH} \mathrm{I}_{2}$ is greatly facilitated by addition of a Lewis acid, it is possible that the addition of a catalytic amount of the proper chiral Lewis acid might further introduce asymmetry into the reaction. Such an approach is currently under investigation.

In summary, we have devel oped a novel class of zinc reagents ( $\mathrm{RXZnCH} \mathrm{Z}_{2} \mathrm{Y}$ ) that can efficiently cyclopropanate olefins. These reagents provide the opportunity to regulate the reactivity and selectivity of cyclopropanations by tuning the electronic and/or steric nature of the RX group on Zn . A reasonable level of enantioselectivity was obtained for the cyclopropanation of unfunctionalized olefins with a chiral (iodomethyl)zinc species. Further studies to expand the scope of these modified zinc reagents and develop an effective enantioselective cyclopropanation of unfunctionalized olefins are currently underway.

## Experimental Section

General Methods. Dichloromethane was distilled from calcium hydride.

Representative Procedure for the Effect of RXH on Cyclopropanation (Method A) (Figure 1). To a solution of $\mathrm{Et}_{2} \mathrm{Zn}$ ( 1.0 M in hexane) ( 1.0 mL , 1.0 mmol ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1 \mathrm{~mL})$ at $-78{ }^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$ was added a solution of $\mathrm{CH}_{2} \mathrm{I}_{2}(0.53 \mathrm{~g}, 2.0$ mmol ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$. After the reaction mixture was stirred at $-15^{\circ} \mathrm{C}$ for 30 min , a solution of RXH ( 1.0 mmol ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added. After an additional 30 min of

[^8]stirring, a solution of trans- $\beta$-methylstyrene ( $0.06 \mathrm{~g}, 0.5 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added. The reaction mixture was then stirred at room temperature. Samples were taken over the course of the reaction and analyzed by GC to determine the conversion.

Representative Cyclopropanation Procedure Using $\mathbf{C F}_{3} \mathrm{CO}_{2} \mathbf{Z n C H}_{2}$ (Method B). To freshly distilled $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (20 mL ) was added $\mathrm{Et}_{2} \mathrm{Zn}$ ( 1.0 M in hexanes) ( $20.0 \mathrm{~mL}, 20.0 \mathrm{mmol}$ ) under $\mathrm{N}_{2}$ (it is best to use an inlet adapter for the nitrogen line since needles often become clogged). The solution was cooled in an ice bath and a solution of trifluoroacetic acid (1.54 $\mathrm{mL}, 20.0 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 10 mL ) was then dripped very slowly into the reaction mixture via syringe. Upon stirring for 20 min , a solution of $\mathrm{CH}_{2} \mathrm{I}_{2}(1.61 \mathrm{~mL}, 20.0 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(10 \mathrm{~mL})$ was added. After an additional 20 min of stirring, a solution of the TBS ether of cinnamyl alcohol ( $2.60 \mathrm{~g}, 10.0$ mmol ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 10 mL ) was added, and the ice bath was removed. After an additional 30 min of stirring, the reaction mixture was quenched with $0.1 \mathrm{~N} \mathrm{HCI}(50 \mathrm{~mL})$ (alternatively with saturated aqueous $\mathrm{NH}_{4} \mathrm{Cl}$ or $\mathrm{Et}_{3} \mathrm{~N}$ fol lowed by saturated aqueous $\mathrm{NaHCO}_{3}$ ) and hexanes ( 25 mL ), and the layers were separated. The aqueous layer was extracted with hexanes. The combined organic layers were washed with saturated $\mathrm{NaHCO}_{3}$, $\mathrm{H}_{2} \mathrm{O}$, and brine and then dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, filtered, concentrated, and purified by column chromatography (hexanes/ether = $50 / 1$ ) to yield the cyclopropane product ( $2.61 \mathrm{~g}, 95 \%$ ).

Representative Procedure for Lewis Acid-Catalyzed Cyclopropanation (Table 2). To a solution of $\mathrm{Et}_{2} \mathrm{Zn}(1.0 \mathrm{M}$ in hexane) ( $1.0 \mathrm{~mL}, 1.0 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1 \mathrm{~mL})$ at $-78{ }^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$ was added a solution of $\mathrm{CH}_{2} \mathrm{I}_{2}(0.53 \mathrm{~g}, 2.0 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$. After the reaction mixture was stirred at -15 ${ }^{\circ} \mathrm{C}$ for $1-2 \mathrm{~h}$, a solution of $\mathrm{CICH}_{2} \mathrm{CH}_{2} \mathrm{OH}(0.079 \mathrm{~g}, 1.0 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1 \mathrm{~mL})$ was added. After 30-45 min of stirring, a solution of trans- $\beta$-methylstyrene ( $0.06 \mathrm{~g}, 0.5 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added. After an additional 15 min of stirring, Lewis acid ( 0.15 mmol ) was added. The reaction mixture was then stirred at room temperature for the indicated time, poured into diluted HCl , extracted with hexanes, washed with saturated $\mathrm{NaHCO}_{3}, \mathrm{H}_{2} \mathrm{O}$, brine, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, and concentrated. The crude product was then analyzed by GC and/ or ${ }^{1} \mathrm{H}$ NMR to determine the conversion.
trans-1-Methyl-2-phenylcyclopropane (Table 3, Entry 1): ${ }^{2 \mathrm{~b}, 8}$ IR (film) $1605,1495,696 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ NMR ( 300 MHz , $\left.\mathrm{CDCl}_{3}\right) \delta 7.27-7.20(\mathrm{~m}, 2 \mathrm{H}), 7.15-7.08(\mathrm{~m}, 1 \mathrm{H}), 7.05-7.00(\mathrm{~m}$, $2 \mathrm{H}), 1.56(\mathrm{dt}, \mathrm{J}=8.8,4.6 \mathrm{~Hz}, 1 \mathrm{H}), 1.18(\mathrm{~d}, \mathrm{~J}=5.7 \mathrm{~Hz}, 3 \mathrm{H})$, $1.04(\mathrm{~m}, 1 \mathrm{H}), 0.88(\mathrm{~m}, 1 \mathrm{H}), 0.73(\mathrm{~m}, 1 \mathrm{H})$; ${ }^{13} \mathrm{C}$ NMR ( 75 MHz , $\mathrm{CDCl}_{3}$ ) $\delta 144.3,128.4,125.7,125.4,24.6,19.3,18.2,17.8$.
