38 Communications synthesis

compounds are 3-ylidenephthalides 2, whose lactone ring is easily opened by nucleophilic bases. As equivalents of 1, 3-benzylidenephthalides (2, $R^2 = C_6H_5$) have been used as starting material for the synthesis of polycondensed nitrogen heterocycles², in the preparation of biologically active substances³,4, in the total synthesis of phthalideisoquinoline alkaloids⁵, and in a new approach to synthesize protopine and protoberberine alkaloids⁶. Moreover, 3-alkylidenephthalides (2, $R^2 = alkyl$) are also found in nature as components of the essential oils of some umbelliferous plants⁷.

A general and extensively used method of preparation of 3ylidenephthalides is the Perkin reaction between phthalic anhydrides (3, $X^1-X^2=O$) and carboxylic acid anhydrides^{3,5,7}. A recent method involves Wittig reaction of phthalic anhydrides with a stabilized phophorane⁸. However, starting from unsymmetrically substituted phthalic anhydrides, these methods lead to mixtures of regioisomers. Thus, in contrast to a published report⁵ concerning the preparation of pure 3-(3,4-methylenedioxybenzylidene)-6,7-methylenedioxyphthalide [(Z)-7bb] by Perkin reaction between 3,4-methylenedioxyphenylacetic acid and 3,4-methylenedioxyphthalic anhydride, we have found that the analogous reaction between the corresponding methoxysubstituted reagents affords a mixture of 3-(3,4-dimethoxybenzylidene)-4,5-dimethoxyphthalide and 3-(3,4-dimethoxybenzylidene)-6,7-dimethoxyphthalide in the ratio 70:30.

To the best of our knowledge, the only reported regiospecific synthesis of 3-ylidenephthalides is the Wittig-Horner-type condensation of aromatic aldehydes and diphenyl 6nitrophthalide-3-phosphonate [3, $R^1 = 6$ -NO₂, $X^1 = H$, $X^2 = PO(OC_6H_5)_2$ obtained by thermal condensation of 5nitrophthalaldehydic acid and diphenyl phosphite⁹. However, the formation of the phosphonate reagent, as well as the generation of the α-phosphonate anion for subsequent nucleophilic reaction with the aldehyde carbonyl, appear to be limited to phthalaldehydic acids bearing a strong electronwithdrawing group. Furthermore, only the condensation with aromatic aldehydes has been reported. Indeed, attempts to achieve the thermal condensation between diphenvl phosphite and phthalaldehydic acids (4a-c) lacking an electronwithdrawing substituent have been unsuccessful in our hands.

We now report an efficient procedure for the preparation of phosphonate reagents $\mathbf{5a-c}$ and their use in Wittig-Horner-type condensations with aromatic aldehydes. Furthermore, one example for the condensation with an aliphatic aldehyde leading to the natural product $\mathbf{7cc}$ is given.

Compounds $4\mathbf{a} - \mathbf{c}$ give good yields of the phosphonates $5\mathbf{a} - \mathbf{c}$ on short exposure to an excess of 30% sodium dimethyl phosphite in methanol followed by acidification of the mixture. Hydroxyphosphonate esters are probable reaction intermediates which lactonize upon acidification. Condensation of $5\mathbf{a} - \mathbf{c}$ with aromatic aldehydes $6\mathbf{a}$, \mathbf{b} to form the benzylidenephthalides 7 is achieved by stirring of the reactants in the presence of sodium hydride in dry tetrahydrofuran for 3 days. Use of alternative conditions such as stirr-

Synthesis of Dimethyl Phthalide-3-phosphonates and Their Use in the Regiospecific Synthesis of 3-Ylidenephthalides

Elio Napolitano*, Guido Spinelli, Rita Fiaschi, Antonio Marsili Istituto di Chimica Organica, Facoltà di Farmacia, Via Bonanno 6, I-56100 Pisa, Italy

Aromatic 1,4-dicarbonyl compounds of general structure 1 are not easily obtained by direct substitution of the benzene ring, except in special cases¹. Major sources of this class of

ing with sodium hydride in dimethylformamide for 15 min or with potassium t-butoxide in tetrahydrofuran for 60 min, although permitting shorter reaction times, result in lower yields of 7 as a result of substantial contamination with 2phenyl-1,3-indanediones. However, such conditions were used for the condensation of 5c with butanal.

As shown by T.L.C. and ¹H-N.M.R. analysis, the double bond formation in the Wittig reaction results in mixtures of (E)/(Z)-isomers. No attempt has been made to separate the geometrical isomers of the benzylidenephthalides. The (E)/(Z)-mixtures of 7 may be used directly for all reactions involving opening of the lactone ring. Furthermore, the isomeric mixtures are converted quantitatively to the more stable (Z)-isomers by opening of the lactone ring with potassium hydroxide in aqueous dioxan followed by recyclization of the intermediate deoxybenzoin-2-carboxylic acid 8 with triethylamine/methyl carbonochloridate in dichloromethane.

Melting points are uncorrected. I.R. spectra were recorded on a Perkin Elmer 195 spectrophotometer and ¹H-N.M.R. spectra on a Varian EM 360 A or on a Varian CFT20 spectrometer. Compounds 4a and 4b were prepared according to reported procedures¹. Dry tetrahydrofuran was distilled from sodium/benzophenone under nitrogen.

Dimethyl Phthalide-3-phosphonates 5a-c; General Procedure:

Dimethyl phosphite (11.0 g, 0.1 mol) and the appropriate phthalaldehydic acid 4 (0.07 mol) are successively added under nitrogen at 0°C to a stirred solution of sodium (2.3 g, 0.1 mol) in methanol (80 ml). After stirring for 30 min at room temperature, methanesulphonic acid (11.0 g, 0.11 mol) is added. Most of the solvent is evaporated under reduced pressure with gentle heating and the residue is partitioned between dichloromethane (200 ml) and cold

40 Communications synthesis

water (50 ml). The organic layer is washed with water (2×50 ml), dried with magnesium sulphate, and evaporated to give crude 5, which is recrystallized from dichloromethane/ether (Table 1).

(E)/(Z)-3-Benzylidenephthalides (E)/(Z)-7; General Procedure:

To a solution of 5 (5 mmol) and aldehyde 6 (6 mmol) in dry tetrahydrofuran (50 ml), sodium hydride (350 mg of a 50 % dispersion in mineral oil, 7.7 mmol) is added and the mixture stirred under nitrogen at room temperature. Stirring is continued until T. L. C. analysis (silica gel plates, ether) indicates the disappearance of starting material 5 (3-4 days). Acetic acid (1 ml) and water (30 ml) are cautiously added to decompose excess sodium hydride and to dissolve inorganic materials. The reaction product may in part precipitate during this operation. The solid is collected by suction and the organic layer evaporated at reduced pressure to give a residue which, together with the solid, is taken up in dichloromethane (150 ml). The resulting solution is washed with water (2 \times 50 ml), dried with magnesium sulphate, and evaporated. The bright vellow residue is collected after trituration with ether. Due to the low solubility of the (E)/(Z)-mixtures of 7 bb in all common solvents, the precipitate obtained is used as such without further purification.

Preparation of Pure Stereoisomers (Z)-7; General Procedure:

The mixture of (E)- and (Z)-7 (2 mmol), 10 molar aqueous potassium hydroxide (0.25 ml, 2.5 mmcl), and dioxan (6 ml) is heated to 100°C in a sealed tube with occas onal shaking for 1 h. The homogeneous solution thus formed is evaporated at reduced pressure, the residue is dissolved in water and the filtered solution, after acidification with dilute hydrochloric acid, extracted with dichloromethane $(3 \times 50 \text{ ml})$. The volume of the dried organic extract is adjusted to ~ 50 ml and the solution, containing the crude deoxybenzoin-2carboxylic acid (8), is treated with triethylamine (1 ml) and methyl chloroformate (1 ml); a strong gas evolution occurs and the solution becomes bright yellow. Pure (Z) 7 is obtained as a bright yellow solid by evaporation of the dichloromethane solution after washing with water (2 \times 20 ml), and dilute hydrochloric acid (20 ml). An analytical sample is recrystallyied from dichloromethane/ether (Table 2). Compound (Z)-7**bb** precipitates as a solid from the reaction mixture, and is collected by suction; the analytical sample is obtained by recrystallization from a large amount dichloromethane.

(E)/(Z)-3-n-Butylphthalide[(E)/(Z)-7cc]:

Compound **5c** (2.4 g, 10 mmol) is dissolved in dry tetrahydrofuran (50 ml) and to the chilled solution potassium *t*-butoxide (1.12 g, 10 mmol) is added with stirring under nitrogen. After 30 min *n*-butanal (**6c**; 0.8 g, 11 mmol) is added. The resulting mixture is stirred for 30 min at room temperature, then diluted with an equal volume of hexane and treated with acetic acid (1 ml). Water (30 ml) is slowly added until two homogeneous phases are obtained. The organic layer is washed with water (50 ml), saturated sodium hydrogen carbonate solution (20 ml), brine (50 ml), and dried with magnesium sulphate. The oily residue obtained by evaporation is bulb to bulb distilled (120 °C/0.01 torr) to obtain a mixture of (*E*)- and (*Z*)-7 cc; yield: 1.5 g (79 %). The (*E*)/(*Z*)-ratio is determined as 20:50 on the basis of the reported ¹H-N.M.R. data⁷. The 2 isomers can be separated by flash chromatography ¹⁰ using dichloromethane as eluent.

A related method^{3,4} using triphenyl-(3-phthalidyl)-phosphonium bromide, also prepared from phthalal-dehydic acids, yields almost pure (E)-3-benzylidenephthalides. In principle, this method is also suitable for the regiospecific synthesis of 3-ylidenephthalides. However, due to the application of the more expensive tri-n-butyl- or triphenylphosphine reagent and the more difficult purification of the products, no particular advantage is offered unless the configuration of the double bond is of importance. Furthermore, the conditions for the preparation of the phosphonium salts may be incompatible with the acid-sensitive substituents in the phthaladehydic acids.
