

Synthesis, Chemical Reactivity, and Cytotoxicity of 2-Bis(alkoxycarbonyl)methyliden-1-azabicyclo[3.1.0]hexane Systems Related to Antitumor Antibiotic Carzinophilin A[†]

Masaru HASHIMOTO, Kaoru YAMADA, and Shiro TERASHIMA*

Sagami Chemical Research Center, Nishi-Ohnuma, Sagamihara, Kanagawa 229

Enantiomeric pairs of the title compounds were synthesized starting from (*S*)- and (*R*)-pyroglutamic acid. They were found to be susceptible to nucleophilic ring opening of aziridine moieties and to exhibit weak *in vitro* cytotoxicity.

Carzinophilin A (Cz-A) (**1**) is an antitumor antibiotic isolated from *Streptomyces sahachiroi* by Hata *et al.* in 1954.¹⁾ While the structure of **1** has been revised several times by plural groups over 30 years,²⁾ Armstrong *et al.* reported in 1991 that ¹H- and ¹³C-NMR spectra of **1** were superimposable on those of azinomycin B.³⁾ The latter compound has been isolated as an antitumor antibiotic from other *Streptomyces* species and carries a characteristic 2-methyliden-1-azabicyclo[3.1.0]hexane ring system.⁴⁾ Since **1** is known as one of the strand cross-linking compounds for DNA,⁵⁾ it is anticipated that, as shown in **2**, the antitumor activity of **1** is probably due to cleavage of the strained aziridine ring by attack of a nucleotide which might effect denaturation of DNA.⁶⁾

Since Armstrong *et al.* recently reported the synthesis of the model compound of Cz-A [(*Z*)-isomer] (**3**),⁷⁾ we wish to report here our own results in this area, culminating in successful preparation of the enantiomeric pair

[†]Dedicated to Professor Emeritus Osamu Simamura of The University of Tokyo on the occasion of his 80th birthday.

of novel 2-bis(alkoxycarbonyl)methyliden-1-azabicyclo[3.1.0]hexane system (**4** and *ent*-**4**) related to **1**. These bicyclic compounds (**4** and *ent*-**4**) were originally designed by expecting that their aziridine moieties could be cleaved in a similar manner to that proposed for **2**. As expected, **4** and *ent*-**4** were found to undergo facile nucleophilic ring opening of their aziridine moieties and, moreover, to exhibit weak *in vitro* cytotoxicity.

The synthesis of **4** and *ent*-**4** commences from optically pure (*S*)- and (*R*)-5-hydroxymethyl-2-pyrrolidone (**5** and *ent*-**5**) obtainable from (*S*)- and (*R*)-pyroglutamic acid according to the reported procedure.⁸⁾ For convenience, the synthetic route employing **5** is shown in Scheme 1. Thus, the hydroxyl group of **5** was first protected in a form of TBDPS ether. The 2-pyrrolidone moiety of the silyl ether was converted into a thiolactam by using Lawesson's reagent,⁹⁾ yielding the pyrrolidin-2-thione (**6**). Treatment of **6** with diethyl or dibenzyl bromomalonate followed by the addition of aqueous KHCO₃ solution resulted in the formation of the 2-bis(alkoxycarbonyl)methylidenpyrrolidines (**7a,b**)¹⁰⁾ in good yields. After the TBDPS ethers of **7a,b** were cleaved by the usual method, the generated alcohols were converted into the tosylates (**8a,b**), which were further transformed into the bromides (**9a,b**) and the iodides (**10a,b**), respectively.

With completion of the synthesis of three types of the reaction substrates (**8-10**), the intramolecular aziridine formation producing a 2-bis(alkoxycarbonyl)methyliden-1-azabicyclo[3.1.0]hexane system was attempted. It was found that treatment of **8a** with potassium hydride in THF at room temperature for 15 min smoothly effected the construction of aziridine ring, giving rise to **4a** in 80% yield based on the ¹H-NMR spectrum of the crude reaction product (crude yield). Since **4a** was quite unstable under acidic conditions (*vide infra*), its isolation

a) TBDPSCl, ImH., DMF, rt, 12 h b) Lawesson's reagent, toluene, reflux, 20 min c) diethyl bromomalonate or dibenzyl bromomalonate, CH₂Cl₂, rt, 12 h, then aq. Scheme 1.

was able to be achieved only by quick Florisil column chromatography, affording a pure sample of **4a** as an oil, $[\alpha]_D^{20} +104^\circ$ (c 0.750, CHCl_3),¹¹⁾ in 34% yield (isolated yield). This rather low yield might reflect that **4a** decomposes during purification process. While **9a** also cyclized to **4a** in 70% crude yield, its isolation in a pure state turned out to be fruitless due to low separation efficiency of **4a** from **9a** by Florisil column chromatography. The cyclization of **8b** to **4b** took place in a very low yield under the same conditions as employed for **8a**. However, desired **4b**¹²⁾ was obtained in 17% isolated yield by using **9b** as a reaction substrate. Long range couplings (1.0 and 0.9 Hz, respectively) between signals of $\text{C}_3\text{-H}_\alpha$ and $\text{C}_6\text{-H}_\alpha$ observed in the $^1\text{H-NMR}$ spectra of **4a,b** as well as NOE experiments carried out on **4a** obviously established the structures of **4a,b** as depicted. It is notable that treatment of **10a,b** under the same conditions as employed for **8a,b** and **9a,b** gave the dimeric products (**11a,b**) in 57% and 70% yields, respectively, after 2 hrs' reactions, although production of a small amounts of **4a,b** was always detected by TLC analysis of the reaction mixture. Accordingly, the formation of **11a,b** might be explained by coupling of produced **4a,b** with the metaloamides of unreacted **10a,b** followed by intramolecular cyclization. Following the same procedures as described above, *ent*-**4a**, $[\alpha]_D^{20} -93.0^\circ$ (c 0.800, CHCl_3), and *ent*-**4b**¹²⁾ were prepared from *ent*-**5**.

Scheme 2.

With **4a,b** and *ent*-**4a,b** in hand, the chemical reactivity of 2-bis(alkoxycarbonyl)methyliden-1-azabicyclo[3.1.0]hexane system was next studied by employing **4a** as a representative substrate. Thus, a pure sample of **4a** was found to be stable in CDCl_3 at 0°C for a week. However, its slow decomposition was observed in MeOH at room temperature, producing the 5-methoxymethylpyrrolidine (**12a**). The $T_{1/2}$ value for the decomposition of **4a** was estimated as *ca.* 2.5 days. Acetic acid reacted with **4a** in THF to afford the 5-acetoxymethylpyrrolidine (**12b**) smoothly. Even under weakly basic conditions, for example, when **4a** was treated with thiophenol in the presence of triethylamine in THF at room temperature, cleavage of the aziridine ring occurred to give the 5-phenylthiomethylpyrrolidine (**12c**). In these experiments, no formation of the 5-substituted piperidine derivatives (**13a-c**) was observed. The structures of **12a-c** were definitely verified by their $^1\text{H-NMR}$ and mass spectra.¹³⁾ Highly regioselective formation of **12a-c** obviously suggests that nucleophilic ring opening of the 2-bis(alkoxycarbonyl)methyliden-1-azabicyclo[3.1.0]hexane systems takes place solely at their C_6 -positions as initially expected.

Finally, *in vitro* cytotoxicity of **4a,b** and *ent*-**4a,b** was examined. Thus, when **4a,b** and *ent*-**4a,b** were subjected to *in vitro* cytotoxicity assay against P388 murine leukemia, the following very weak cytotoxicity was observed for these compounds [IC_{50} ($\mu\text{g/mL}$): 0.74 (**4a**), 11.6 (**4b**), 3.1 (*ent*-**4a**), and 7.6 (*ent*-**4b**)].

As described above, we have succeeded in preparing **4a,b** bearing a novel 2-bis(alkoxycarbonyl)methyliden-1-azabicyclo[3.1.0]hexane system related to **1** and in exploring their chemical reactivity and *in vitro* cytotoxicity. Based on these results, synthetic studies aiming at the second generation of the model compound of **1** are in progress in these laboratories.
