## ABSTRACT

Indium(III) halide catalyzed not only the coupling of alkyl chlorides with silyl enolates derived from esters, ketones, and aldehydes to give a variety of  $\alpha$ -alkylated carbonyl compounds but also one-pot, three-component reactions of aldehyde enolate, alkyl chloride, and allylsilane or alkynylsilane.

A coupling reaction of organic halides with metal enolates is one of the most useful protocols for carbon–carbon bond formation in organic synthesis. A topic of current interest is the catalytic activation for coupling using less expensive organic chlorides. In particular, a reaction using unactivated organic chlorides remains to be a challenge. For this study, our group focused on the reaction of alkyl chlorides with silyl enolates, which are both stable and mild reagents, hence requiring activation by a Lewis acid. Although Reetz et al.<sup>1,2</sup> reported the coupling of alkyl chlorides with silyl enolates catalyzed by  $\text{ZnCl}_2$  or  $\text{ZnBr}_2$ , the applicable substrates had strict limitations. Our group has recently demonstrated the catalytic ability of indium species using moderate Lewis

acidity to effect Freidel–Crafts alkylation.<sup>3</sup> The present study deals the  $\text{InBr}_3$ -catalyzed coupling reaction of alkyl chlorides with aldehyde-, ketone-, and ester-derived silyl enolates.

First, the reaction of benzyl chloride **1a** with dimethylketene methyl trimethylsilyl acetal **2a** was investigated in the presence of various catalysts (Table 1). A 5 mol % loading of  $\text{InBr}_3$  was found to give the coupling product **3aa** quantitatively in  $\text{CH}_2\text{Cl}_2$  at room temperature (entry 2). By comparison,  $\text{InCl}_3$  gave a low yield (entry 3).  $\text{ZnBr}_2$  and  $\text{ZnCl}_2$ <sup>4</sup> had lower catalytic ability than  $\text{InBr}_3$  and  $\text{InCl}_3$ , respectively (entries 4 and 5). Other typical Lewis acids such as  $\text{BF}_3\cdot\text{OEt}_2$ ,  $\text{AlCl}_3$ , and  $\text{TiCl}_4$  were ineffective to afford the product **3aa** (entries 6–8). These results are perhaps because these catalysts might have highly oxophilic coordination with silyl enolate rather than activating the alkyl chloride.  $\text{BiBr}_3$ ,

8	TiCl <sub>4</sub>	0
9	BiBr <sub>3</sub>	0

<sup>a</sup> Alkyl chloride **1a** (1 mmol), silyl enolate **2a** (1.5 mmol), catalyst (0.05 mmol), and CH<sub>2</sub>Cl<sub>2</sub> (1 mL).

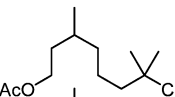

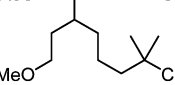

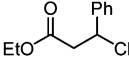

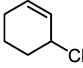

reported as a moderate Lewis acid, however, showed no effect (entry 9).<sup>5</sup>

Second, various alkyl chlorides and silyl enolates were treated, and the results are summarized in Table 2. Unactivated aliphatic chlorides **1b** and **1c** effectively produced the coupling products **3ba** and **3ca**, respectively (entries 1 and 2). It is an advantage of the indium catalyst that oxygen-containing functionalities are applicable (entries 3–5). The coupling with allylic chloride **1g** produced the corresponding ester **3ga** in high yield (entry 6). Both benzyl chlorides, bearing an electron-withdrawing or -donating group, gave satisfactory yields (entries 7 and 8). Silyl enolates **2b** and **2c**, derived from ketones, reacted with 1-chloro-1-phenylethane **1j** to yield the desired substituted ketones in high yields (entries 9 and 10). Interestingly, thioester and amide enolates **2d** and **2e** furnished the substituted thioester **3kd** and amide **3ke**, respectively (entries 11 and 12). This is the first example of coupling of alkyl chlorides with silyl enolates derived from thioesters and amides.

The alkyl chloride **1l** having a bromo moiety selectively provided the chloro-coupling product **3la** in 82% yield (Scheme 1). On the contrary, employment of Hiyama-coupling conditions using a palladium catalyst promoted an alternate coupling at the bromo moiety to furnish the dehydrochlorinated products **4** and **5**.<sup>6</sup>

Most studies have focused on enolates derived from esters and ketones, while a few have been done using silyl enolates derived from aldehydes, in part due to a lower nucleophilicity.<sup>7,8</sup> In addition, the expected end products have a formyl moiety which reacts easily with the starting enolates and

<sup>a</sup> Alkyl chloride **1** (1 mmol), silyl enolate **2** (1.5 mmol), InBr<sub>3</sub> (0.05 mmol), and CH<sub>2</sub>Cl<sub>2</sub> (1 mL). <sup>b</sup> Silyl enolate **2** (3 mmol). <sup>c</sup> InCl<sub>3</sub> (0.05 mmol) was added instead of InBr<sub>3</sub>. <sup>d</sup> Silyl enolate **2** (2 mmol). <sup>e</sup> Diastereomer ratio: 52:48.

leads to a complicated mixture. However, once the desired aldehyde products are effectively in hand, they make good synthetic building blocks. Our study examined various types of aldehyde enolates (Table 3). The reactions of enolate **2f** with unactivated alkyl chloride **1b** and benzylic chlorides **1a** and **1j** resulted in the corresponding aldehydes **3** (entries 1–5). Silyl enolates **2g** and **2h**, derived from butanal and acetaldehyde, were not applied to this reaction system (entries 6 and 7) because these enolates were decomposed by the indium(III) halide.<sup>9</sup> Silyl enolates derived from more hindered aldehydes **2i** and **2j** gave the desired aldehydes **3ji** and **3jj**, respectively.

In our study, a tentative mechanism in which alkyl chloride was activated by InBr<sub>3</sub> to produce a carbocation was

(9) When InBr<sub>3</sub> and an aldehyde enolate were mixed, the formation of a complicated mixture was observed. Probably the enolate easily changed to α-silyl aldehyde under the conditions, and the enolate reacted with the formed α-silyl aldehyde.

proposed (Scheme 2, type **A**). The reaction with silyl enolate gave the desired ester and  $\text{Me}_3\text{SiCl}$  with a regeneration of  $\text{InBr}_3$ . An indium(III) halide activated alkyl halide selectively and weakly interacted with silyl enolate because of its high halophilicity.<sup>10</sup> In contrast, a high oxophilicity was the reason the strong Lewis acids such as  $\text{AlCl}_3$  and  $\text{BF}_3\cdot\text{OEt}_2$  showed no activity. The reaction may accelerate with the combined Lewis acid of  $\text{InBr}_3$  and  $\text{Me}_3\text{SiCl}$  (type **B**) generated in situ because in the combined form it acted as a strong Lewis acid.<sup>3</sup> The coupling reaction was catalyzed by both systems.

Next, we envisioned a three-component reaction in which the generated aldehyde was to immediately react with

**Scheme 2.** Plausible Mechanism

allylsilane. This idea was based on our previous report of a Hosomi–Sakurai reaction catalyzed by the combined Lewis acid of  $\text{InCl}_3$  and  $\text{Me}_3\text{SiCl}$ .<sup>11</sup> After the reaction of alkyl chloride **1i** with silyl enolate **2f** was complete, allylsilane **6a** was added to the resulting mixture at room temperature. This step-by-step process yielded the homoallyl alcohol **7ifa** in 76% yield (see the Supporting Information). Next, the three components **1i**, **2f**, and **6a** in the presence of  $\text{InBr}_3$  were mixed (Scheme 3). Surprisingly, when the mixture was

<sup>a</sup> Alkyl chloride **1** (1 mmol), silyl enolate **2** (2 mmol),  $\text{InBr}_3$  (0.05 mmol), and  $\text{CH}_2\text{Cl}_2$  (1 mL). <sup>b</sup> Silyl enolate **2** (3 mmol). <sup>c</sup> The reaction was run at  $-78\text{ }^\circ\text{C}$ . <sup>d</sup>  $\text{InCl}_3$  (0.05 mmol) was added instead of  $\text{InBr}_3$ . <sup>e</sup> Diastereomer ratio: 59:41. <sup>f</sup> Diastereomer ratio: 65:35.

gradually warmed from  $-78\text{ }^\circ\text{C}$  to room temperature, the desired selective tandem reactions took place prior to the coupling of **1i** and **6a**. The addition of alkynylsilane **6b** instead of **6a** gave propargyl alcohol **7ifb** in 73% yield.  $\text{InBr}_3$  is a good catalyst that promotes both coupling and addition reactions and also controls the reaction order.

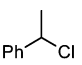

Finally, our system had another advantage with respect to solvents. Most of the previous Lewis acid-catalyzed reactions of organic chlorides with silyl enolates have been conducted in a halogenated solvent such as  $\text{CH}_2\text{Cl}_2$ ,<sup>12</sup> while a reaction in non-halogenated solvents is essential for green

<sup>a</sup> Alkyl chloride **1** (1 mmol), silyl enolate **2a** (1.5 mmol), catalyst (0.05 mmol), hexane (1 mL).

chemistry. Our system using InBr<sub>3</sub> was effective in hexane solvent (Table 4). These results were inferior to those in CH<sub>2</sub>Cl<sub>2</sub>, but satisfactory yields were secured (entries 1, 3, and 5). Under the same conditions, ZnBr<sub>2</sub> was ineffective (entries 2, 4, and 6), but InBr<sub>3</sub>-catalyzed systems removed the restrictions of the solvent.

In conclusion, our study demonstrated the coupling reactions of alkyl chlorides with silyl enolates catalyzed by InBr<sub>3</sub> or InCl<sub>3</sub>. This reaction system was applied to aldehyde enolates and the three-component sequential carbon–carbon bond formation between alkyl chloride, aldehyde enolate, and other silyl nucleophiles. In addition, the coupling reaction effectively occurred in a non-halogenated solvent such as hexane. Further detailed studies are in progress.
