ABSTRACT

N,N-Dialkyl- β -amino alcohols derived from α -amino acids can be rearranged enantiospecifically by using TFAA/Et₃N/NaOH to give 1,2-amino alcohols with enantiomeric excess up to 99%.

β -Amino alcohol moieties are present in a large variety of naturally occurring and pharmacologically active molecules.¹ The amino alcohol relative stereochemistry is highly important for the biological activity of these molecules. These entities can also be used as chiral auxiliaries in asymmetric synthesis.^{2,3}

Linear *N,N*-dialkyl- β -amino alcohols have been shown to rearrange, via an aziridinium ion, into β -halogenoamines (on treatment with SOCl₂,⁴ MsCl,⁵ TsCl,⁵ SOBr₂,⁶ CBr₄/PPh₃,⁷ DAST,⁸ or Deoxofluor⁹), into β -mesylamines (on treatment with Ms₂O^{10,11}), and into thiocyanates (on treatment with

KSCN¹²). Recently we have shown that prolinols can be rearranged enantiospecifically to give optically active piperidin-3-ols, via an aziridinium intermediate, by using TFAA/Et₃N/NaOH.^{13,14} In this Letter, we would like to report that these latter conditions can be applied to linear optically active β -amino alcohols of type **A** to produce 1,2-amino alcohols of type **B** in a very regio-, stereo-, and enantioselective process (Scheme 1).

N,N-Dibenzyl- β -amino alcohols **2a**,¹⁵ **2c**,⁵ **2e**,¹⁶ **2f**,¹⁷ **2g**, and **2h**¹⁸ were prepared from the commercially available amino alcohols by using benzyl bromide (2.2 equiv) in the

Scheme 1

presence of K_2CO_3 (3 equiv) and *n*-tetrabutylammonium iodide (0.3 equiv) in refluxing acetonitrile (Table 1). *N,N*-Dibenzyl- β -amino alcohols **2b** and **2d** are commercially available.

Table 1. Synthesis of *N,N*-Dibenzylamino Alcohols

entry	R	product (yield)
1	Ph	2a (79%)
2	BnOCH ₂	2c (76%)
3	<i>i</i> -Pr	2e (81%)
4	<i>t</i> -Bu	2f (75%)
5		2g (67%)
6		2h (96%)

The optically active amino alcohol (*R*)-**2i** was synthesized from the racemic phenylglycine **3**. Esterification with $SOCl_2$ in ethanol followed by treatment with benzaldehyde furnished the corresponding imine **4**. After alkylation under catalytic phase transfer conditions (AllylBr, *n*-Bu₄NHSO₄, NaOH, CH₂Cl₂) and hydrolysis of the imino group, the racemic amino ester **5** was obtained in 75% yield. The resulting α -allylphenylglycine ethyl ester **5** was subjected to a kinetic enzymatic resolution by using lipase PLE¹⁹ to provide the (*R*)-enantiomer of **5** in 45% yield and 91% enantiomeric excess.^{20,21} This latter compound was then converted to the corresponding amino alcohol (*R*)-**2i** in 57% yield by reduction with $LiAlH_4$, followed by bis-*N*-benzylation with benzyl

bromide (K_2CO_3 , *n*-Bu₄NI, CH₃CN, microwaves irradiation, 120 °C, 3 h) (Scheme 2).

Scheme 2

N,N-Dibenzylamino alcohols **2a–i** were treated with trifluoroacetic anhydride (TFAA, 1.5 equiv) and Et₃N (2 equiv) and heated at 100 °C under microwave (MW) irradiation. After 2 h, the reaction mixture was treated with NaOH (3.75 N) to provide the *N,N*-dibenzyl- β -amino alcohols **6a–i** in good yields and with excellent enantiomeric excess (Table 2).²² The (*S*)-absolute configuration of **6a**²³ was determined by comparison of the $[\alpha]_D$ of the (*S*)-*N,N*-2-dibenzylamino-1-phenylethanol synthesized from the commercially available (*S*)-2-amino-1-phenylethanol. The (*R*)-absolute configuration was established for compounds **6b**,²⁴ **6d**,²⁴ and **6e**²⁵ by comparison of the $[\alpha]_D$ reported in the literature. We have to point out that in the case of amino-1,3-diol **2h** the amino-1,2-diol **6h** was obtained in 66% yield indicating that the reaction is very regio- and diastereoselective. Furthermore, almost no loss of chirality was observed in the case of the amino alcohol **6i**, possessing a tertiary hydroxyl group, as it was obtained from **2i** with 63% yield

The stereospecificity of this reaction can be rationalized by the intermediacy of an aziridinium ion of type **E**.¹³ This aziridinium is formed from the ammonium trifluoroacetate ester **C**, which is transformed to the aziridinium **E**, via the amino ester **D**, after treatment with Et₃N. As a trifluoroacetate anion is liberated into the reaction media, this anion can attack the more substituted carbon atom of the aziridinium **E**, producing the aminoester **F**. By analogy with the work of Gmeiner,¹⁰ we assume that compounds **D** and **F** are in equilibrium, and that the secondary trifluoroacetate ester **F** is the thermodynamic product. After saponification of **F**, amino alcohols of type **B** are liberated (Scheme 3). Due to the high ee observed in the rearrangement it is unlikely that the reaction proceeds via a planar carbocation intermediate.

Scheme 3(26) Seco, J. M.; Quiñoá, E.; Riguera, R. *Tetrahedron: Asymmetry* **2001**, 12, 2915–2925.(27) Fiaux, H.; Popowycz, F.; Favre, S.; Schütz, C.; Vogel, P.; Gerber-Lemaire, S.; Juillerat-Jeanneret, L. *J. Med. Chem.* **2005**, 48, 4237–4246.

The treatment of 1,2-amino alcohols with TFAA/Et₃N/NaOH is a very powerful procedure that allows the synthesis of β -amino alcohols of type **B** with high yield and enantiomeric excess. Furthermore, the *N,N*-dibenzyl- β -amino alcohols of type **B** can be used to provide chiral 2-amino-1-alkylethanol by hydrogenolysis of benzyl groups.²⁵ Further
