# Nanocomposite copper metal as an efficient heterogeneous catalyst in click synthesis of 1,2,3-triazoles in aqueous media

Vajihe NEJADSHAFIEE, Hossein NAEIMI\*

Department of Organic Chemistry, Faculty of Chemistry, University of Kashan, Kashan, Iran

<b>Received:</b> 23.10.2016	•	Accepted/Published Online: 20.03.2017	•	<b>Final Version:</b> 10.11.2017
-----------------------------	---	---------------------------------------	---	----------------------------------

**Abstract:** Copper/periodic mesoporous organosilica (Cu/PMO) nanocomposites provided a highly active, reusable, globular, solid-phase catalyst for click chemistry. The reaction proceeds by mixing organohalides, sodium azide, alkyne, and the catalyst in an aqueous medium to afford the desired products. The cost efficiency and recyclability of the catalyst up to six runs without appreciable loss of activity and high yields of products make this procedure greener.

Key words: Mesoporous, organosilica, nanocomposites, click reaction, 1,2,3-triazoles, catalyst

### 1. Introduction

Click chemistry has become one of the most important concepts in modern chemistry, focusing on efficiently creating molecular diversity from readily available starting materials under simple reaction conditions.<sup>1</sup> Copper (I)-catalyzed organoazide–alkyne cycloaddition (CuAAC)<sup>2</sup> was one of the most credible click-type reactions within the concept of click chemistry. $^{3-5}$  This reaction has enabled the practical and efficient preparation of 1,2,3-triazoles from a wide range of substrates with excellent selectivity that cannot be prepared via traditional Huisgen uncatalyzed thermal approaches.<sup>6</sup> Triazoles have attracted considerable interest recently because of their wide usefulness. Among them, 1.2,3-triazoles have received much attention and have been used in variety of synthetic and medicinal chemistry applications such as drug discovery,<sup>7</sup> material science,<sup>8</sup> and bioconjugation.<sup>9</sup> In this regard, heterogeneous catalysis emerges as an important tool and has been frequently used as a green alternative for a broad range of chemical transformations. With the finding that copper metal can be a catalytic species for the synthesis of 1,2,3-triazoles,<sup>10,11</sup> efforts have been devoted to develop new catalytic systems, including heterogeneous catalysis processes, especially copper nanoparticles.<sup>12–17</sup> Additionally, it brings important advantages, such as easy recovery (removal of the catalyst from the reaction media by simple filtration), easy recycling, and enhanced stability of the catalyst, and reactions in water, the solvent used by nature for biological chemistry, which can make synthetic processes cheaper, safer, and greener.  $^{18-20}$  Regarding our continuous search for reactions catalyzed by mesoporous silica structures as new nanocatalysts, we dedicated our efforts to develop a safe, easy to handle heterogeneous catalyst that could be easily separated from the crude reaction mixture and recycled in a given process.  $^{21,22}$ 

Previous studies showed that Cu/PMO nanocomposite, synthesized by the sol-gel method, was successfully employed to promote three-component  $\beta$ -hydroxy-1,2,3-triazoles synthesis, known as the click reaction, with different methods (Scheme 1).<sup>23–25</sup> We wish to disclose herein our results regarding the performance and

scope of Cu/PMO nanocomposite catalyst in the domino azidolysis of aryl halides and 1,3-dipolar cycloaddition with alkynes, in which 1,2,3-triazoles were synthesized in high yields and short reaction time in aqueous media. A catalyst in amounts of 0.47 mol % promoted the Huisgen 1,3-dipolar cycloaddition of organic azides and terminal alkynes and it was reused without loss of catalytic activity or leaching of copper species.

Scheme 1. Multicomponent synthesis of  $\beta$ -hydroxy-1,2,3-triazoles from styrene oxide, phenylacetylene, sodium azide catalyzed by Cu/PMO NCs in water.

#### 2. Results and discussion

#### 2.1. Preparation of the catalyst

The copper catalyst was readily available by imprinting periodic mesoporous organosilica (PMO) with a recently prepared complex of copper. The latter was obtained by sol-gel process from copper acetate monohydrate, Schiff base, cetyl trimethyl ammonium bromide (CTAB) tetraethylorthosilicate (TEOS), and 3chloropropyltrimethoxysilane in deionized water under hydrothermal condition (see Supporting Information).

In contrast with most heterogeneous catalysts, our catalyst was ready for use as prepared, after filtration and drying, without any further pretreatment.

The catalyst was fully characterized by different methods, which revealed the presence of copper imprinted on the PMO (Figures 1-7 of the Supporting Information).

In order to develop an efficient protocol for the Huisgen 1,3-dipolar cycloaddition, a mixture of benzyl chloride, NaN<sub>3</sub>, and phenyl acetylene was reacted with different amounts of catalyst, temperatures, and times (Table 1).

As can be seen, the optimized reaction conditions were 0.47 mol % of catalyst and temperature of 60 °C.

After independent optimization of the reaction conditions, different substituted organohalides was efficiently reacted with alkynes under similar conditions to afford the corresponding 1,2,3-triazoles in yields of 82%–96% (Table 2). All the 1,2,3-triazoles were isolated by crystallization. The development of Cu/PMO nanocomposite catalyst with high catalytic efficiency and reusability was our major purpose for this reaction.

The reaction mechanism in the alkyne-organoazide cycloaddition catalyzed by Cu/PMO nanocomposite arises from the formation of copper acetylides or copper  $\pi$ -complexes as the real intermediates. On the other hand, the formation of copper (I) triazolide complex as intermediate in the click reaction has been often postulated. Final protonolysis of this type of intermediate would render the triazole product (Scheme 2).

Scheme 2. Mechanistic considerations.

### 2.2. Compared to some of the catalysts reported

A comparative study on the reactivity of the Cu/PMO nanocomposite with the some reported catalysts of copper to the reaction of benzyl chloride, phenylacetylene, and sodium azide in the optimized condition was carried out, as summarized in Table 3. However, the Cu/PMO nanocomposite was shown to be more active, a low copper loading (0.47 mol %) and mild reaction conditions in comparison with the other catalysts (Table 3, entries 8 vs. 1-7). As can be observed from this table, much higher yields, short reaction times, a low copper loading (0.47 mol %), and mild reaction conditions were obtained for 1.2,3-triazoles with our catalyst in comparison with the other catalysts.

## 2.3. Recyclability of the catalyst

When using a supported catalyst, there is an important problem that the catalyst is readily reusable, which makes its usage an excellent alternative, especially considering environmental and economic aspects. The Cu@PMO NCs catalyst was recovered by the fitted glass filter during filtration, and it was reused in the same reaction under similar conditions without loss of catalytic activity for 6 cycles (Figure).

Figure. Recyclability of the Cu@PMO NCs catalytic system.

## 3. Conclusion

We developed a reusable Cu/PMO NCs catalyst that effectively catalyzed the Huisgen 1,3-dipolar cycloaddition of a variety of alkynes and organic azides, including the three-component cyclization of a variety of alkynes, organic halides, and sodium azide. The products were obtained in good yields with a dramatic reduction in the reaction times and the catalyst was shown to be easily recoverable from the reaction. Moreover, an important feature shown by the catalyst is that it can be reused at least six times without significant loss of activity.

### 4. Experimental section

All chemicals were purchased from Fluka, Merck, and Aldrich chemical companies. For recorded <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra we used a Bruker DRX-400 in pure deuterated DMSO-d<sub>6</sub> solvent with tetramethyl silane (TMS) as the internal standard. FT-IR spectra were obtained as KBr pellets on a PerkinElmer 781 spectrophotometer and on an impact 400 Nicolet FT-IR spectrophotometer. TGA was carried out on an STA503 WinTA analyzer from 25 to 900 °C under nitrogen with a heating rate of 10 °C min<sup>-1</sup>. The XRD patterns were recorded on an X-ray diffractometer (Bruker, D8 ADVANCE, Germany) using Cu-Ka radiation ( $\lambda = 0.154056$  nm) in the range  $2\theta = 0.5-5^{\circ}$ . The N<sub>2</sub> adsorption/desorption analysis (BET) was performed at -196 °C using an automated gas adsorption analyzer (Tristar 3000, Micromeritics). The scanning electron microscopy (SEM) image was recorded on a JEOL 6400 scanning electron microscope operated at 15 kV.

### 4.1. General procedure for the synthesis of 1,2,3-triazoles using Cu/PMO NCs

The click reaction of organohalides and alkynes was carried out with treatment of NaN<sub>3</sub> (72 mg, 1.1 mmol), organohalide (1 mmol), alkyne (1 mmol), and Cu/PMO NCs (10 mg, 0.47 mol %) in H<sub>2</sub>O (3 mL). The reaction mixture was warmed to 60 °C and monitored by TLC until total conversion of the starting materials. After completion of the reaction, the reaction mixture was filtered off. In order to separate the catalyst from the products, the reaction mixture was dissolved in hot ethanol; subsequently, the whole mixture was directly passed through a sintered glass filter funnel and the excess of solvent was removed under reduced pressure to give the corresponding 1,2,3-triazole compounds (Table 1). Most of the products are known and all of the isolated products gave satisfactory IR and NMR spectra (see Supporting Information).

# **Supplementary Information**

A typical procedure for the synthesis of Schiff base and its complex (1, 2): Schiff base (1) was synthesized by dissolving melamine (0.126 g, 1.0 mmol) and salicylaldehyde (0.214 g, 2 mmol) in 5 mL of methanol and the presence of three drops of acetic acid and the reaction mixture was heated under reflux at 100 °C for 4 h. After the completion of the reaction, the Schiff base product was filtered, then washed with water, and dried at ambient temperature, resulting in the formation of orange solid in 98% yield. IR (KBr): v = 3468, 3416, 3332, 3129, 1654, 1552, 1439, 1272.

To prepare the complex (2) (copper-ligand preorganized complex), the Schiff base (0. 332 g, 1 mmol) was dissolved in 15 mL of dimethylformamide and treated with copper acetate monohydrate (Cu(OAc)<sub>2</sub>. H<sub>2</sub>O), heated under reflux for 3 h. Finally, the formed metal–ligand complex was filtered, washed with 96% ethanol (100 ml) and dried for 1 day under vacuum to produce complex as brown crystals in 95% yield. IR (KBr): v = 3466, 3419, 3343, 3131, 1650, 1548, 1438, 1204.

A typical procedure for the synthesis of copper-imprinted organopolysilane precursor (3): The copper-imprinted organopolysilane precursor (3) was obtained as follows: 0.5 g (1.3 mmol) of complex (2) was dissolved in 60 mL of dry ethanol. To this, 0.5 mL (2.6 mmol) of 3-chloropropytrimethoxysilane was added dropwise under a N<sub>2</sub> atmosphere in the presence of NaH as a base and ascorbic acid as reducing agent for reduction of the copper (II) (2) to copper (I) (3). The reaction mixture was stirred at 60 °C for 24 h under nitrogen atmosphere. Subsequently, the reaction mixture was filtered, concentrated under vacuum, purified with diethylether (3 × 50 mL), and dried under vacuum and copper-imprinted organopolysilane precursor (3) was obtained in 90% yield. IR (KBr): v = 3402, 2922, 2852, 1558, 1460, 1266.

A typical procedure for the synthesis of Cu@PMO NCs: PMO was synthesized using a previously reported procedure [1] along with modification. In a typical procedure, 1.0 g of CTAB (2.74 mmol) was dissolved in 47 mL of distilled water. The solution was stirred for 10 min, followed by the addition of 11 mL of ammonia (25%) and stirred for a further 30 min to obtain a clear solution. A premixed propanol solution of organopolysilane precursor (**3**) and TEOS were added to the surfactant solution. The molar composition of the final synthetic mixture was TEOS: ion-imprinted organopolysilane precursor (**3**): CTAB: NH<sub>3</sub>: H<sub>2</sub>O: propanol =

(1 + x): x: 0.12: 8.0: 114: 7; where x = 0.05 for Cu@PMO NCs, respectively. The reaction mixture was stirred at 35 °C for 24 h. Then the final mixture was crystallized at 90 °C for 24 h. The resulting solid was filtered and washed with deionized water, and dried in a vacuum at 60 °C for 12 h. The surfactant was removed by extracting the solid with a 0.05 M ethanolic HCl solution at 60 °C for 6 h (50 mL of 0.05 ethanolic HCl for 1 g of solid material). The obtained material was designated as Cu/PMO NCs.

Scheme 1. Different steps for preparation of Cu/PMO NCs.

## Characterization of Cu@PMO NCs Catalyst:

# 1,1-[2,4,6-Triyl-1,3,5-triazinebis(nitrilomethylidine)]bis-(phenol) Schiff base (1).

Orange solid: mp. 237 °C (decomposed). <sup>1</sup>H NMR (400 MHz, DMSO) δ= 10.71 (s, 1H, O–H), 10.24 (s, 1H, CH=N), 7.65 (m, 2 H, aromatic), 7.50 (m, 2 H, aromatic), 6.98–6.63 (m, 4 H, aromatic), 6.04 (s, 2H, N–H).

Figure 1. <sup>1</sup>H NMR of Schiff base (1).

The  $N_2$  adsorption–desorption isotherm and pore size distribution of Cu/PMO NCs hybrid mesoporous silica framework is shown in Figure 2. The isotherm exhibited type IV patterns with H3 hysteresis loops, which is a characteristic of mesoporous solids<sup>1</sup>. The values of surface area, pore size, and pore volumes are presented in Table 1.

**Figure 2.** N<sub>2</sub> adsorption–desorption isotherm (A) and pore size distribution curve (B) of Cu@PMO NCs.

 Table 1. BET surface area, BJH pore diameter, pore volume, and wall thickness of Cu@PMO

 NCs.

Sample	BET surface area $(m^2 g^{-1})$	BJH pore diameter (nm)	Poe volume ( $cm^3 g^{-1}$ )	d 100 (nm)	Wall thickness <sup>a</sup> (nm)
Cu@PMO NCs	462.40	3.98	0.50	4.41	1.11

<sup>a</sup> wall thickness=  $a_0$ -pore diameter

TGA of Cu@PMO NCs is shown in Figure 3. According to the thermogram, there is 3%–4% weight loss within a temperature range of around 100–300 °C, which is due to the loss of adsorbed water molecules. Furthermore, it shows that a degradation process occurs between 300 and 483 °C and the weight loss is about 11%–12%. This is due to the breakdown of copper-imprinted periodic mesoporous organosilica nanocomposites groups imprinted to the PMO.

Figure 3. TGA thermograms of Cu@PMO NCs.

Figure 4 shows the SEM image of the Cu@PMO NCs, which contain many short rods. Moreover, this surface morphology of the NPs catalyst is indicative of the presence of a wellordered mesostructure with hexagonal lattice arrangements.

Figure 4. FE-SEM images of Cu@PMO NCs.

For Cu@PMO NCs, the obtained results by EDS were as follows (%): C, 18.42; N, 7.09; Cu, 0.43; Si, 24.73; O, 49.34 (Figure 5). The EDS analysis confirmed the presence of Schiff base-copper complex (**2**) on PMO.

Figure 5. EDS pattern of Cu@PMO NCs.

The well-ordered mesostructural arrangement of the Cu@PMO NCs hybrid was confirmed by low angle XRD. Figure 6 shows the low angle XRD patterns of Cu@PMO NCs. The three reflection peaks corresponding to  $2\theta = 0.5-5^{\circ}$  of  $1.05^{\circ}$ ,  $1.9^{\circ}$ , and  $2.3^{\circ}$  were indexed to the (100), (110), and (200) reflections, respectively, which are clearly indicative of the presence of a well-ordered mesostructure of the materials with hexagonal lattice arrangements.

Figure 6. XRD spectrum of Cu/PMO NCs.

FT-IR spectrum of Schiff base (1), complex (2), and Cu@PMO NCs is shown in Figure 7. The spectrum provides evidence for the presence of functional moieties in the imprinted mesoporous silica hybrids (Figure 7a). The C=N stretching vibration frequency of Cu@PMO NCs was observed at 1561 cm<sup>-1</sup>. The vibration bands at 2853 and 2923 cm<sup>-1</sup> were assigned to the C–H stretching vibrations of propyl and methyl groups, respectively. The vibration peak at 1474 cm<sup>-1</sup> was characteristic of N–C vibrations of the aromatic functional groups present in the Cu@PMO NCs. The band in the range 1000–1100 cm<sup>-1</sup> was assigned to Si–O–Si groups and the band at 961 cm<sup>-1</sup> was attributed to Si–OH groups. A broad band in the region, 3367 cm<sup>-1</sup>, was assigned to the O–H stretching vibrations of surface silanols on Cu/PMO NCs (Figure 7a).

Figure 7. FT-IR spectra of a) Cu@PMO NCs, b) Schiff base (1) c), complex (2).
