## Abstract

*N*-fluorobis[(perfluoroalkyl)sulfonyl]imides,  $\text{CF}_3\text{SO}_2\text{N}(\text{F})\text{SO}_2\text{R}'$  ( $\text{R}' = \text{C}_4\text{F}_9, \text{C}_6\text{F}_{13}, \text{C}_8\text{F}_{17}$ ) and  $(\text{C}_4\text{F}_9\text{SO}_2)_2\text{NF}$ , were prepared by direct fluorination of corresponding N–H compounds using elemental fluorine without a solvent in good to excellent yields. All of these N–F compounds are electrophilic fluorination agents and can easily deliver “F<sup>+</sup>” to certain molecules. Their reactions with aromatic rings, beta-diketones, and alkenes were investigated to compare their fluorination power. © 2001 Elsevier Science B.V. All rights reserved.

**Keywords:** Electrophilic fluorination; *N*-fluorosulfonimides

## 1. Introduction

In the past 20 years, a lot of effort has been directed towards discovering safer and more selective electrophilic fluorinating agents, which surmount some of the difficulties associated with perchloryl fluoride, elemental fluorine and hypofluorites. As a result of these efforts, a number of N–F compounds have been synthesized and found to be generally better sources of electrophilic fluorine for selective fluorinations [1,2]. While many other electrophilic N–F reagents have been developed and several are commercial, none of these possess the reactivity and utility of *N*-fluorobis[(perfluoroalkyl)sulfonyl]imide reagents [3].

The first and simplest compound of this type was *N*-fluorobis[(trifluoromethyl)sulfonyl]imide (**1a**) that was synthesized and shown to work as an efficient reagent for the selective fluorination of a variety of substrates [3]. It has excellent long-term stability, desirable physical properties and high reactivity [4–11].

In order to further study and evaluate the synthetic potential of *N*-fluorobis[(perfluoroalkyl)sulfonyl]imides, a variety of  $\text{R}'\text{SO}_2\text{N}(\text{F})\text{SO}_2\text{R}'$  (**1b–e**) were synthesized. Their reactivities in several selective fluorinations were then compared.

## 2. Results and discussion

### 2.1. Synthesis of *N*–F compounds

Bis[(perfluoroalkyl)sulfonyl]imides (**2**), the precursors of **1**, were prepared according to the synthetic route developed by us [12] as shown in Scheme 1. All steps except the preparation of triflic anhydride have excellent yields (95–98%). Recently  $(\text{CF}_3\text{SO}_2\text{N})_2\text{Li}$  is available from 3 M Co and both the acid and lithium salt are available from Aldrich. Bis[(perfluoroalkyl)sulfonyl]imides are extremely hygroscopic, and all procedures should be carried out under anhydrous conditions.

*N*-fluorobis[(perfluoroalkyl)sulfonyl]imides were prepared by the direct fluorination of corresponding N–H precursors (Scheme 2).

In earlier preparation of **1a–b**, Singh et al. [3] and Witz et al. [12] introduced F<sub>2</sub> in one portion into a stainless steel bomb containing the N–H compound at –196°C. But sometimes an uncontrolled overreaction occurred during warm-up, and led to low yields. An improved procedure in which fluorine gas is introduced in portions has replaced the older method. In the fluorination of 30 g (107 mmol) of **2a** 10% excess F<sub>2</sub> was introduced in portions according to Table 1 at –196°C. After each fluorine addition, the liquid nitrogen bath was removed and the bomb was allowed to warm to 22°C and remain at 22°C for several hours. After fluorination was complete, **1a–b** were purified by trap-to-trap distillation after the removal of co-product HF by forming NaHF<sub>2</sub> with NaF.

Scheme 2.

Table 1  
Time table of fluorination of  $(\text{CF}_3\text{SO}_2)_2\text{NH}$  (107 mmol)

Time (h)	Amount of $\text{F}_2$ introduced (mmol)
0	5
2	15
6	30
10	30
15	38 (118 total, 10% excess) <sup>a</sup>

<sup>a</sup> The bomb was allowed to stand at 22°C for 8 h after this addition.

The same method was used to prepare **1c–e**, and isolation of the pure compounds was possible by removal of the HF under vacuum at 0°C, followed vacuum distillation from any unreacted acid. The reaction of the N–H compounds becomes much slower with increasing size of the  $\text{R}_f$  group (Table 2). Heating at 50–60°C is necessary to obtain high conversion of the acids to the N–F derivatives. Surprisingly, the heating results in little or no degradation of the starting acid or the N–F product. The marked difference in reactivity

Table 2  
Preparation of N–F compounds

N–F compound	Fluorination conditions	N–F ( $\delta$ )	Yield (%)
<b>1b</b>	22°C, ~1 day	–32.4	81
<b>1c</b>	50–60°C, ~10 days	–32.3	80
<b>1d</b>	50–60°C, ~10 days	–32.3	92
<b>1e</b>	50–60°C, ~10 days	–31.3	98

could be due to a number of factors, including the structure of the solid acid, lower solubility of the acid in the product HF and perhaps low vapor pressure of the starting acid. Originally we had reported that **1e** could not be prepared at 22°C [3]. Higher reaction temperatures were not attempted based on the obviously incorrect assumption at that time that heating would lead to degradation. In fact, all the N–F compounds exhibit excellent thermal stability as determined by DSC measurements. The onset of decomposition was: **1b** 190°C; **1c** 200°C; **1d** 205°C; **1e** 150°C. Clearly the stability appears to be about the same as one  $\text{R}_f$  group increases in size, but is lower with two larger  $\text{R}_f$  groups. Differences in thermal stability may be due to the presence of a liquid phase for a longer time in the small, sealed, stainless steel DSC capsule for the larger  $\text{R}_f$  groups. For **1a**, we have not determined the decomposition under conditions where liquid **1a** would be present.

## 2.2. Fluorination reactivity studies

N-fluorobis[(trifluoromethyl)sulfonyl]imide (**1a**) is the most reactive among known N–F compounds [13]. We believe its fluorination power comes from the extraordinary electron withdrawing ability of two  $\text{CF}_3\text{SO}_2$  groups as related to the acidity of the parent sulfonimide  $(\text{CF}_3\text{SO}_2)_2\text{NH}$  (**2a**). Koppel et al. [14] have measured the gas phase acidity of many perfluorinated sulfonimides and found that **2b–e** were more acidic than **2a** with  $(\text{C}_4\text{F}_9\text{SO}_2)_2\text{NH}$  (**2e**) presently holding the record as the strongest measured gas phase superacid. We wondered if these acidity differences might be reflected in the fluorination power of the corresponding N–F compounds. Also of interest were the possible steric effects of the larger  $\text{R}_f$  groups on reactivity. Based on the limited reactivity studies with these N–F agents with 1,3-dicarbonyl derivatives,  $\alpha,\beta$ -unsaturated carbonyl compounds, and aromatic rings, we found no significant differences between the reactivity of **1a–e**.

All of these N–F agents can readily undergo reaction with neutral  $\beta$ -diketones and  $\beta$ -ketoesters in  $\text{CH}_2\text{Cl}_2$  at 22°C to afford predominantly mono-fluorinated products (Scheme 3). The solubility of **1c–e** in  $\text{CH}_2\text{Cl}_2$  was relatively

Scheme 3.

low, but reaction proceeded readily. But for other much slower reactions with  $\alpha,\beta$ -unsaturated carbonyls, solubility appeared to be the rate-determining factor. If  $\text{CH}_2\text{Cl}_2/\text{CH}_3\text{COOH}$  was used as solvent, reaction of *trans*-4-phenyl-3-buten-2-one with **1e** was much slower than the same reaction with **1a**. But when the solvent was changed to dry  $\text{CH}_3\text{CN}/\text{CH}_3\text{COOH}$ , both reactions finished within 10 h.

All the reactions were carried out using one equivalent of the N-F reagents, so mono-fluorination was the major product, with small amounts of difluorinated product formed in the fluorination of substrate **3**. In the reactions of substrates **5** and **7**, two major isomers (*erythro*- and *threo*-) were obtained, but separation was not carried out.

Activated aromatics such as phenol, toluene, aniline, etc. can be smoothly fluorinated by **1a** at  $22^\circ\text{C}$  [3]. Here biphenyl and diphenylmethane were compared with **1a** and **1e** in dichloromethane and acetonitrile solvents. Again in acetonitrile the delivery of F to the aromatic ring is much faster than that in  $\text{CH}_2\text{Cl}_2$ . Preference for *o*-fluorination was observed in all cases with the *o*-/*p*- ratio ranging from 1.5 to 3.2.

### 3. Experimental section

IR spectra were taken as neat films on KCl using a Perkin-Elmer FT-IR spectrometer SPECTRUM 2000.  $^1\text{H}$  and  $^{19}\text{F}$  NMR spectra were obtained on a Bruker AC-200 instrument at 200.13 and 188.31 MHz, respectively. Chemical shifts are given in ppm from internal TMS for  $^1\text{H}$  NMR spectra and

from internal  $\text{CFCl}_3$  for  $^{19}\text{F}$  NMR spectra.  $\text{CDCl}_3$  was the solvent for  $^{19}\text{F}$  NMR as well as for  $^1\text{H}$  NMR, unless otherwise noted. Mass spectra were measured with a Hewlett Packard 5985B GC/MS spectrometer. Column chromatography was performed on silica gel (100–200 mesh).

#### 3.1. Materials

Bis[(perfluoroalkyl)sulfonyl]imides (**2a–e**) were prepared according to methods reported previously (Scheme 1). The solvents used for the reactions were dried by standard methods before use. Other commercially available compounds were used without further purification.

#### 3.2. General procedure for preparation of *N*-fluorobis(perfluoroalkyl)sulfonimides (**1a–b**)

Inside a dry box, bis[(trifluoromethyl)sulfonyl]imide (**2a**) (107 mmol) was placed into a 500 ml stainless steel bomb. The bomb was cooled to  $-196^\circ\text{C}$  and evacuated. Excess fluorine gas (118 mmol) was then introduced in portions according to Table 1. After each addition of fluorine, the liquid nitrogen bath was removed and the bomb was allowed to warm to  $22^\circ\text{C}$ . After the final portion of  $\text{F}_2$  was introduced, the bomb was kept at  $22^\circ\text{C}$  for 8 h. The reactor was then cooled to  $-196^\circ\text{C}$  and excess  $\text{F}_2$  was removed under dynamic vacuum through a soda-lime column. The remaining mixture was vacuum transferred into another stainless steel bomb containing 10 g of NaF and shaken at  $22^\circ\text{C}$  for ca. 5 min

to allow the complete absorption of HF by NaF. Then the pure product was obtained as a colorless liquid by trap-to-trap distillation (0,  $-70$ ,  $-196^{\circ}\text{C}$ ; product in  $-70^{\circ}\text{C}$  trap); **1a**:  $^{19}\text{F}$  NMR  $\delta$   $-33.5$  (N–F),  $-72.0$  (6F); **1b**: IR  $\nu$  ( $\text{cm}^{-1}$ ) 1465(s), 1235(vs), 2150(s), 1022(w), 889(m), 849(m), 738(w), 703(w), 638(w), 584(w);  $^{19}\text{F}$  NMR  $\delta$   $-32.4$  (N–F),  $-72.3$  (3F),  $-81.2$  (3F),  $-106.0$  (2F),  $-120.7$  (2F),  $-126.1$  (2F).

### 3.3. General procedure for preparation of *N*-fluoroperfluoroalkylsulfonimides (**1c–e**)

Inside a dry box, **2d** (7.1 mmol) was placed into an 80 ml stainless steel bomb. The bomb was cooled to  $-196^{\circ}\text{C}$  and evacuated. Excess fluorine gas (12.1 mmol) was then introduced in one portion. After addition of fluorine, the liquid nitrogen bath was removed and the bomb was heated to  $50$ – $60^{\circ}\text{C}$  for 10 days. The bomb was cooled to  $-196^{\circ}\text{C}$  and excess fluorine was removed as above. The bomb was then warmed to  $0^{\circ}$  in an ice-water bath and connected to a dynamic vacuum through a FEP trap ( $-196^{\circ}\text{C}$ ) for about 10 min. All of the product HF was transferred into that FEP trap and pure N–F product remained inside the bomb as a colorless liquid. **1c**: IR  $\nu$  ( $\text{cm}^{-1}$ ) 1464(s), 1360(w), 1235(vs) 1150(s) 1022(w), 889(m), 849(m) 739(w), 703(w), 638(w), 585(w);  $^{19}\text{F}$  NMR  $\delta$   $-32.3$  (N–F),  $-72.0$  (3F),  $-81.1$  (3F),  $-105.8$  (2F),  $-119.7$  (2F),  $-121.8$  (2F),  $-123.0$  (2F),  $-126.5$  (2F); **1d**: IR  $\nu$  ( $\text{cm}^{-1}$ ) 1465(s), 1233(vs), 1152(s), 986(w), 861(m), 733(w), 707(w), 659(w), 584(w);  $^{19}\text{F}$  NMR

$\delta$   $-32.3$  (N–F),  $-72.3$  (3F),  $-81.0$  (3F),  $-105.8$  (2F),  $-119.7$  (2F),  $-121.7$  (4F),  $-122.2$  (2F),  $-123.2$  (2F),  $-126.6$  (2F); **1e**: IR  $\nu$  ( $\text{cm}^{-1}$ ) 1464(s), 1351(s), 1208(vs), 1145(s), 1025(m), 845(m), 801(m), 739(m), 699(w), 651(w), 570(w);  $^{19}\text{F}$  NMR  $\delta$   $-31.3$  (N–F),  $-81.1$  (3F),  $-106.0$  (2F),  $-120.8$  (2F),  $-126.2$  (2F).

### 3.4. General procedure for fluorination of ethyl 4-nitrobenzoylacetate

Into a  $\text{CH}_2\text{Cl}_2$  (15 ml) solution of ethyl 4-nitrobenzoylacetate (**3**, 2.0 mmol) was added 0.1 g of anhydrous  $\text{Na}_2\text{CO}_3$  and 2.0 mmol of N–F at  $22^{\circ}\text{C}$  and the reaction mixture was stirred for 8 h. The reaction mixture was diluted with ethanol (10 ml) and water (50 ml), extracted by  $\text{CH}_2\text{Cl}_2$  (10 ml  $\times$  2 ml), rinsed with brine and dried over  $\text{Na}_2\text{SO}_4$ . Pure ethyl 2-fluoro-3-(4'-nitrophenyl)-3-oxo-propanoate (**4**) was obtained by column chromatography on silica gel using hexane/ethyl acetate [9], **4**:  $^{19}\text{F}$  NMR  $\delta$   $-190.86$  (d,  $^2J_{\text{HF}} = 48.4$  Hz).

### 3.5. General procedure for fluorination of $\alpha,\beta$ -unsaturated carbonyl compound

The N–F reagent (1.0 mmol) was dissolved in 2 ml of solvent (Table 3) and added dropwise into the solution of  $\alpha,\beta$ -unsaturated carbonyl compound. The mixture was then stirred at  $22^{\circ}\text{C}$  for the desired time. Simple column
