Some spiro[piperidine-4,2'-(1'H)-quinazolin]-4'-(3'H)-ones **3 and spiro[piperidine-4,5'-(6'H)-[1,2,4]triazolo[1,5-c]quinazolines **4** were synthesized and evaluated as ligands of the nociceptin receptor. The examined compounds showed partial agonistic activity, except compounds **3**, **4n** that proved to be pure antagonists.**

Key words spiro[piperidine]; spiro[piperidine triazoloquinazoline]; nociceptin receptor ligand; opioid

The nociceptin (NOP) receptor is the latest identified member of the transmembrane G-protein coupled receptors family comprising δ , κ and μ opioid receptors.¹⁾

Its original homology cloning and the isolation from brain extracts of the endogenous ligand, the heptadecapeptide nociceptin (NC),^{2,3)} gave rise to a great interest in clarifying its physiological functions. The receptor, distributed in both central and peripheral nervous systems and in non-neuronal tissues, revealed to be involved in several processes including modulation of nociception,^{2,3)} locomotor activity,³⁾ reversal of stress-induced analgesia,⁴⁾ modulation of learning and memory,^{5–7)} regulation of neurotransmitter and hormone release,^{8,9)} neuronal differentiation.^{10,11)}

In the last years NOP receptor has become an important biological target for a number of potential therapeutic applications associated with pain, stress and anxiety, cognitive deficiency, eating and other disorders.¹²⁾ At the same time, consistent advances have been attained in the design and discovery of new ligands, and many nonpeptide small molecules were developed as agonists or antagonists.^{13–17)}

Among several scaffolds, spiro[piperidines] showed to be an interesting and promising class of NOP ligands. They are structurally related to lofentanyl (Fig. 1), a μ -selective opiate ligand having also affinity for the NOP receptor.

The NOP active site^{18,19)} was first investigated by computational studies on its complex with nociceptin^{20,21)} and lofentanyl.²¹⁾ Anyway spiro[piperidines]²²⁾ were useful tools for the elucidation of the mechanism of interaction of small non peptidic molecules. These studies indicated the electrostatic interaction of protonated piperidinic nitrogen with Asp130 and a hydrogen bond between the small molecule and Thr305 as determinant features for affinity.

Most of the spiro[piperidines] have been reported to possess high agonistic activity and selectivity as Ro 64-6198¹⁴⁾ (Fig. 1) which also exhibited anxiolytic properties.

The interest in this scaffold of compounds also relies in their capability of reversing their biological effect after small structural modifications. Some antagonists developed by Banyu¹⁵⁾ (Fig. 1) that differ from their “isomer” Ro 64-6198 in the imidazolinone amidic sequence, can be mentioned as an example.

The intriguing and often complex structure–activity relationships of spiro[piperidinic] NOP ligands led us to synthe-

size a series of new spiro[piperidine-quinazolinones **3** and spiro[piperidine-triazoloquinazolines **4** whose structure partly recalled some very potent agonists by Roche¹⁶⁾ (Fig. 1). Our aim was to explore the influence of the following structural features on affinity and selectivity:

- the presence of a fused benzene ring instead of the typical *N*-phenyl substituent
- the inversion of the NH–CO sequence respect to the lead molecules
- the different length and branching of the alkylsubstituent on the cyclohexane ring
- the substitution of the amidic moiety by a fused triazole ring.

Results and Discussion

Chemistry The synthetical pathway to the target compounds is outlined in Fig. 2.

The 1-substituted piperidones **2** were obtained by reaction

of the 1-ethyl-1-methyl-4-oxopiperidinium iodide **1**²³⁾ with the corresponding amines in a hydroalcoholic medium in the presence of sodium carbonate at reflux. The reaction of **1** with 4-alkylcyclohexylamines used as isomeric mixtures,²⁴⁾ gave the expected *cis* and *trans* isomers which were separated by column chromatography on aluminium oxide or silica gel by eluting with ethyl acetate/hexane mixtures. The assignment of their configuration was performed by ¹H-NMR in pyridine-*d*₅ solution. The *cis* isomer always eluted first.

Compounds **2** were allowed to react with anthranilamides in an acetic acid–sulfuric acid mixture to give spiro compounds **3**. Reaction of **2** with 2-([1,2,4]triazol-3-yl)aniline²⁵⁾ in the same acidic medium gave the [1,5-*c*] fused compounds **4**.

*N*6'-Methylation of compounds **4d cis** and **4e cis** was achieved by reaction with formic acid and sodium borohydride to give **4m cis** and **4n cis** respectively.

In order to obtain an experimental evidence that we had [1,5-*c*] and not [4,3-*c*] ring fusion, we synthesized the 5,6-dihydro-[1,2,4]triazolo[1,5-*c*]quinazoline by reduction of the [1,2,4]triazolo[1,5-*c*]quinazoline²⁵⁾ with sodium borohydride and observed that its H-2 signal in the ¹H-NMR spectrum in DMSO-*d*₆ had the same position (δ =8.04 ppm) of the corresponding H-2' protons in compounds **4**.

Pharmacology The binding affinities of the synthesized compounds were measured by employing [¹²⁵I]-nociceptin as radiotracer. The most active compounds were also tested on δ , κ and μ receptors to estimate their selectivity towards all the opioid receptor subtypes. In such experiments we used [³H]-naltrindole for δ , and [³H]-diprenorphine for κ and μ as radioligands. The results are shown in Tables 1 and 2.

The biological efficacy of the compounds was evaluated as their ability to enhance the binding of [³⁵S]GTP γ S in the presence of GDP, using membranes isolated from cells transfected with NOP receptors. This assay, based on GTP/GDP exchange on the G protein α subunit, is a direct measure of receptor-mediated G protein activation (Fig. 3). The membranes were prepared from a cell line expressing a tandem fusion protein between the NOP receptor and the α subunit of G_o. As previously reported²⁶⁾ the forced 1 : 1 stoichiometry of expression of receptor and G α subunit in such system greatly enhances the GTP γ S response and allows to detect even small levels of ligand efficacy.

Moreover, for the *cis* compounds **3d, e, m, n, s, t** and **4d, e, m, n** we scanned the [³⁵S]GTP γ S binding response at a wide range of GDP concentrations in order to reveal the full or partial agonism and the antagonism, of these compounds (Fig. 4).

The *cis* compounds **3m, 3n, 4m** and **4n** were also tested for their potency to affect nociceptin-stimulated GTP γ S binding. The dose-response curves are reported in Fig. 5.

Binding Affinity for NOP Receptor The most active compounds (IC₅₀ values <10 μ M) are reported in Table 1. The compounds **3f, g, i** and their *N*¹-methylated analogues **3o, p, r**, bearing the aromatic substituent benzyl, phenethyl and dibenzosuberyl on the piperidine nitrogen atom, showed low affinity and have not been taken into account in the selectivity and intrinsic activity experiments.

The binding data of 4-alkylcyclohexyl derivatives indicated that branched alkyl groups, *iso*-propyl for **3d, m, s** and **4d, m** and *tert*-butyl for **3e, n, t** and **4e, n**, enhanced potency

Fig. 2. Synthetical Route to Compounds **3** and **4**

compared to linear methyl, ethyl and propyl substituents (**3a–c, 4a–c**).

In both series **3** and **4** the *cis* conformers showed a higher affinity than their *trans* isomers. This configurational effect resulted more evident in the *iso*-propyl derivatives **3d, m**, whose *cis* isomers were about 20 folds more active than their corresponding *trans*.

Methylation or benzylation on the quinazolinone *N*¹ tended not to affect the affinity of the ligands while *N*¹-benzylation of the less active compounds **3d trans** and **3f**, led to a 10-fold increased affinity (**3f** IC₅₀=50.8 μ M, **3u** IC₅₀=5.1 μ M).

The substitution of the amide function HN₃–C₄=O with the isosteric triazole ring, to give compounds **4**, resulted in a general increase of potency mainly for the *N*-methyl and *N*-ethylcyclohexyl compounds **3a, b**.

In conclusion, the binding studies suggest two essential structural requirements for the affinity: a bent molecular

The binding of [35 S]GTP γ S was measured at increasing GDP concentrations as indicated on x-axis, in the absence (BAS) or in the presence of the ligands. Compounds **3n cis** and **4n cis** exhibit lack of stimulation at all concentrations of GDP.

Fig. 5. Antagonism of Nociceptin-Mediated Activation of G_{a_o} Induced by Compounds **3n cis** and **4n cis**

Concentration–response curves for nociceptin-mediated stimulation of [35 S]GTP γ S in the presence of 300 nM GDP were performed in membranes expressing the ORL $_1$ R- G_{a_o} fusion protein as described in Experimental. Curves were generated in the absence and presence of increasing concentrations of either **3n cis** (A) or **4n cis** (B), as indicated. Data points, after subtraction of basal activity (specific binding measured in the absence of nociceptin) were plotted as fractional effect by dividing all values for the net cpm stimulated by 10 nM nociceptin in the control curve of each experiment. Data were analysed using ALLFIT (see Experimental), to compute the EC_{50} in the absence and presence of the various concentrations of antagonist. Insets: Schild analysis of the data. The log of the shift induced by each agonist (*i.e.* ratio of EC_{50} in the presence vs. absence of antagonist minus one, $S-1$) is plotted as a function of the log of the antagonist concentration. Linear regression analysis of the data gave the following results ($\pm$ standard error): (A) slope 0.82 ± 0.06 , x value at $y=0$ (pA_2), 5.71 ± 0.38 ; (B) slope 0.89 ± 0.06 , x value at $y=0$ (pA_2), 5.71 ± 0.38 .

tive compounds **3** and **4** were tested for selectivity on the opioid δ , κ and μ receptors (Tables 1, 2). In general compounds **3** tended to be more selective than triazoles **4**. They all

showed no affinity for the δ and a moderate to good selectivity towards the μ subtype, whereas the κ subtype selectivity ratio resulted lower. Adamantyl substituted **3h** was the most selective compound showing a selectivity ratio higher than 100 for δ , κ and μ receptors.

These quinazolinone and triazoloquinazoline spiroderivatives tended to possess higher κ vs. μ affinity compared to analogue spiropiperidines bearing a *N*-phenylimidazolinone ring.¹⁶⁾ These results confirm the hypothesis that the heterocyclic portion may be mainly responsible for selectivity in these structures.²⁷⁾ The tetrahydroquinazoline moiety featuring compounds **3** and **4**, seems to be more suitable for interaction with the κ receptor.

Biological Efficacy The biological efficacy of compounds **3** and **4** expressed as ability to enhance the binding of [35 S]GTP γ S in the presence of GDP, in membranes from cells transfected with NOP receptors, is reported in Fig. 3. This assay is a direct measure of the receptor-mediated G-protein activation.

The examined compounds showed a variable partial agonistic activity that gradually decreased to pure antagonism in *tert*-butyl N^1 -methyl derivatives **3n cis** and **4n cis**. The results reported in the histogram (Fig. 3) evidenced that the higher efficacy was related to the presence of the *iso*-propyl substituent. Other structural features, as *cis* or *trans* configuration, seemed not to be directly related to the biological effect, although the highest activities both as regards partial agonism and antagonism were associated to compounds in the *cis* configuration (**3d cis**, **3e cis**, **3s cis**, **4d cis**, **4m cis**, **3n cis** and **4n cis**).

A study at several GDP concentrations confirmed the partially agonistic character of all compounds and the antagonism of **3n cis** and **4n cis**.

In Fig. 4 the dose–response curves for the *cis* compounds **3d**, **3e**, **3m**, **3n**, **3s**, **3t**, **4d**, **4e**, **4m** and **4n** are reported as an example.

To analyze the mechanism of antagonism exerted by compounds **3n cis** and **4n cis** we performed a classical Schild analysis.²⁸⁾ We measured the effects of increasing concentrations of the antagonist on the concentration–response curves

of nociceptin. Both compounds induced a rightward shift of the nociceptin-stimulated binding of [35 S]GTP γ S without changing the maximum agonist stimulation (Fig. 5). The corresponding K_i determined by the Schild plots, was 1.2×10^{-7} M (**3n cis**) and 3.7×10^{-7} M (**4n cis**), in good agreement with binding results. The slope of the Schild plot (0.82 ± 0.06 , 0.89 ± 0.06 respectively) indicated both compounds as competitive antagonists.

Molecular Modeling Studies To get a deeper insight into the molecular bases of the interaction between NOP receptor and the synthesized compounds, molecular modeling techniques were employed.

All the calculations were conducted on a Silicon Graphic Octane R10000 workstation, within the Sybyl 6.91 software package (Tripos, Inc. St. Louis, MO, U.S.A.).

The partial agonists *N*¹-H **3d cis**, **3e cis**, **4d cis** and **4e cis** and their *N*¹-methyl derivatives **3m cis**, **3n cis**, **4m cis** and **4n cis** were taken into account. The pure agonist Ro 64-6198¹⁴⁾ and the pure antagonist Banyu¹⁵⁾ were also investigated as a comparison.

The most stable molecular conformation was determined by a simulated annealing protocol (10 cycles, heating the system up to 2000 K in 1000 fs, annealing subsequently to 0 K in 2000 fs) followed by a geometrical optimization (through the semi-empirical molecular orbital approach provided by the MOPAC 2000²⁹⁾ program package) and a systematic search on the single bond between the piperidine and

the R substituent (30° steps). The structures were generated assuming that the molecules were protonated on the piperidine nitrogen.

Subsequently each ligand was manually docked into the binding site of the NOP receptor²²⁾ in the middle of the transmembranes (TM) 3, 5, 6 and 7 at the head of the receptor (Fig. 7A) and between two pockets: the first one formed by Leu104, Gly108, Val126, Ile127, Ile198, Glu199, Cys200, Leu201, Leu301, Tyr309 and the second one formed by Tyr131, Met134, Phe135, Ile204, Phe215, Phe220, Phe224, Trp276, Val279, Val283. The Asp130 was chosen as an anchoring residue, as suggested by Tophan *et al.*³⁰⁾

Energy minimisation followed the docking, therefore the lower energy structure of the protein–ligand complex was predicted together with the biologically active conformation of each ligand.

This procedure highlighted the possibility that each *cis* *N*¹-H compound **3d**, **3e**, **4d** and **4e** could form two isoenergetic complexes with the NOP receptor, while *N*¹-methylated **3m**, **3n**, **4m** and **4n** presented only one way of docking to the receptor. All the generated protein–ligand complexes shared the following interactions:

a) a salt-bridge between Asp130 and the protonated piperidine nitrogen. This interaction has been established to be fundamental amongst many NOP ligands^{21,22)} and it is of utter importance in the binding of nociceptin itself to its receptor.^{18,21)}

b) various dispersive interactions between the aromatic moiety and the lipophilic residues in the first pocket and other dispersive interactions between the alkylcyclohexyl substituent of the ligands and the lipophilic residues in the second pocket.

Moreover the first complex of *cis* compounds **3d**, **3e**, **4d** and **4e** with NOP receptor showed a hydrogen bond (2.5–2.7 Å) between the carbonyl oxygen of the quinazolinone ring or triazoloquinazoline *N*¹-nitrogen and the hydroxyl group of Thr305, and a quite strong hydrogen bond (1.5 Å) between the hydrogen at the *N*¹-position of the quinazolinone ring and the carbonyl oxygen of Cys200 (Fig. 7B1).

In the second complex the same compounds pointed the *N*¹-H group to Thr305 forming a hydrogen bond acting as donors (Fig. 7B2).

These results agreed with the models proposed for the complexes between NOP receptor and nociceptin¹⁸⁾ and NOP receptor with other potent agonists.²²⁾

*N*¹-Methylated *cis* **3m**, **3n**, **4m** and **4n** bound the receptor by a moderate interaction of the quinazolinone carbonyl (**3m**, **n**) or triazoloquinazoline C^{10b}=*N*¹ (**4m**, **n**) groups with Thr305 hydroxyl group.

These results highlighted the ligand molecular groups involved in the binding affinities but did not provide any information about structural requirements responsible for intrinsic activity. In fact on the basis of molecular modeling studies we could not explain why only the methylated *cis* *tert*-butyl derivatives **3n** and **4n** showed antagonist activity. In this series of compounds we can only hypothesize that the simultaneous presence of chemical groups as methyl and *tert*-butyl conferred to the ligands an optimally sized and directed conformation able to inactivate the receptor.

Conclusions

We have synthesized a series of new spiro[piperidine-4,2'-(1'*H*)-quinazolin]-4'-(3'*H*)-ones and of spiro[piperidine-4,5'-(6'*H*)-[1,2,4]triazolo[1,5-*c*]quinazolines] that displayed moderate to good affinity for the NOP receptors and behaved as partial agonists.

The peculiarity of this scaffold of ligands is that the substituent on the *N*¹-position of the piperidine ring affected the affinity and modulated the efficacy. Moreover the presence of a methyl substituent on the quinazoline *N*¹ joined to the presence of a *tert*-butylcyclohexyl tail led to a loss of the intrinsic activity.

Molecular modeling on the complexes with the NOP receptor suggested that the non-conservative aminoacid Thr305 together with Asp130 can be considered of critical importance in the interaction of spiropiperidines with NOP receptor. The recent hypothesis that efficacy of spiropiperidines is also related to a lipophilic interaction between the cycloalkyl substituent and the receptorial hydrophobic second pocket neighbouring the Asp130,²⁷⁾ has also been confirmed.

In summary, our series of compounds could be further exploited as tools for studying receptor interactions as related to biological efficacy.

Experimental

Melting points were determined on a Köfler hot stage apparatus, unless otherwise stated, and are uncorrected. Column chromatographic separations were accomplished on Merck silica gel (70–230 mesh) or on Merck aluminium oxide 90. The purity of each compound was checked on silica gel C. Erba 60 F₂₅₄ or Merck aluminium oxide 60 F₂₅₄ (type E) plates and spots were located by UV light. Sodium sulfate was used to dry organic solutions. Analyses indicated by the symbols of the elements were within ±0.4% of the theoretical values.

The ¹H-NMR spectra and COSY experiments were performed on Bruker Avance 700 and 400 instruments in pyridine-*d*₅, in order to improve the spectral resolution of the aliphatic region, or in CDCl₃ or DMSO-*d*₆ solution; all values are reported in ppm (δ) and standard abbreviations were used (a=apparent; b=broad; d=doublet; dd=doublet of doublets; dt=doublet of triplets; m=multiplet; q=quadruplet; qt=quintet; s=singlet; sh=sharp; t=triplet; tt=triplet of triplets, u=unresolved).

Electron Ionisation Mass spectra were recorded on a HP 59980 B spectrometer operating at 70 eV.

Amantadine was obtained from its commercial hydrochloride by displacement with aqueous sodium hydroxide. The 5*H*-10,11-dihydrodibenzo[*a,d*]cyclohepten-5-amine was prepared according to the literature.³¹⁾ The 4-substituted cyclohexylamines were obtained, in the form of *cis*-*trans* isomeric mixture,²⁴⁾ by reduction with lithium aluminium hydride of the corresponding oximes, which was performed in refluxing tetrahydrofuran according to a conventional procedure³²⁾; 1-benzyl-4-piperidone **2e** and 1-phenethyl-4-piperidone **2f** were purchased by Fluka.

General Procedure for the Preparation of the 1-Substituted 4-Piperidones 2 To a suspension of the appropriate amine (0.02 mol) and sodium carbonate (1.4 g, 0.013 mol) in refluxing ethanol (60 ml) under stirring, was dropwise added a solution of **1**²³⁾ (8.1 g, 0.03 mol) in water (20 ml), and the mixture refluxed for 2 h. The resulting solution was evaporated *in vacuo* to remove ethanol, then strongly alkalized with 20% aqueous sodium hydroxide and extracted with ethyl acetate. The organic phase was dried over sodium sulfate and evaporated *in vacuo*. The residue was chromatographed on silica gel by eluting with a 1 : 1 ethyl acetate–hexane mixture in the case of **2e** or on aluminium oxide by eluting with a 1 : 3 ethyl acetate–hexane mixture for the other compounds.

General Procedure for the Preparation of the 1'-Methyl-spiro[piperidine-4,2'-(1'*H*)-quinazolin]-4'-(3'*H*)-ones 3j—r A solution of the appropriate piperidine **2** (0.01 mol) and 2-methylaminobenzamide³⁴ (1.5 g, 0.01 mol) in acetic acid (14 mL) with two drops of sulfuric acid, was refluxed for 30 min; then the mixture was cooled, diluted with water, alkalized with 8% aqueous sodium hydroxide and repeatedly extracted with ethyl acetate. The organic phase was then dried over sodium sulfate, evaporated *in vacuo* and crystallized from the appropriate solvent.

NOP Receptor Binding Assay in Membrane Preparations Enriched plasma membranes from transfected cells were prepared by differential centrifugations³⁷ and stored at –80 °C (protein concentration 2–4 mg/ml) until used. The binding of [¹²⁵I]-Tyr₁₄-nociceptin (Perkin Elmer Life Sciences) was measured in 1 ml reaction mixture containing 50 mM Hepes–Tris pH 7.4, 10 mM MgSO₄, 10 μM leupeptin, 10 μM bestatin, 0.1 mg/ml bacitracin, 0.1% (w/v) bovine serum albumin (BSA), and 3 μg of membrane proteins from HEK-293 cells transfected with the NOP receptor as previously described.²⁶ The concentration of radiotracer was maintained constant at 50000–100000 cpm in the presence of increasing concentrations of compounds to be tested. Reactions lasted 90 min at room temperature and were terminated by rapid filtration onto GF/B glass fiber filtering microplates pretreated with 0.1% Ethylene Imine Polymer (PEI) (Filtermate 196; Packard Instruments, Meriden, CT). Filters were washed three times with 1 ml of ice-cold 50 mM

Tris-HCl pH 7.4 and allowed to dry for 30 min at 37 °C. The plates were counted in a Top Count (Packard Instruments) after the addition (50 µl) of Microscint 20 (Packard) to each well.

IC₅₀ values were obtained by fitting the competition curves according to a 4-parameter logistic model (ALLFIT program).³⁸⁾

δ, κ, μ Receptors Binding Assay The binding affinities for human δ, κ and μ receptors were determined with [³H]-naltrindole for δ receptor and with [³H]-diprenorphine for κ and μ receptors.^{39,40)}

A suspension of membranes (5–15 µg) of HEK-293 cells expressing δ receptors²⁶⁾ and κ receptors (Perkin Elmer Life Sciences) and of CHO cells expressing μ receptors (Perkin Elmer Life Sciences) was incubated with the radioligand (30000–50000 cpm) at room temperature for 2 h in a total volume of 1 ml containing 50 mM Hepes-Tris pH 7.4, 100 mM NaCl, 0.1 mg/ml bacitracin, 0.1% (w/v) BSA and increasing concentrations of compounds to be tested. Samples were incubated for 90 min at room temperature, filtered onto GF/B glass fiber filtering microplates (Filtermate 196; Packard Instruments, Meriden, CT, U.S.A.) and washed three times with 1 ml of ice cold 50 mM Tris-HCl pH 7.4 prior to scintillation counting on a Packard Top Count.

IC₅₀ values were obtained by fitting the competition curves according to a 4-parameter logistic model (ALLFIT program).³⁸⁾

GTPγS Binding The ³⁵S GTPγS binding was determined in a 1 ml reaction mixture containing 50 mM Hepes-Tris pH 7.4, 1 mM dithiothreitol (DTT), 100 mM NaCl, 10 mM MgSO₄, 0.1 nM ³⁵S GTPγS (Perkin Elmer Life Sciences), 300 nM GDP (or concentrations varying between 0.1 nM and 100 µM) and 1–2 µg of membrane proteins, with or without compounds to be tested.²⁶⁾ The dose-response curves of nociceptin were determined in absence and in presence of fixed concentrations of the tested compounds (0.1, 1, 100 µM).⁴¹⁾ Samples were incubated for 90 min at room temperature, filtered onto GF/B glass fiber filtering microplates (Filtermate 196; Packard Instruments, Meriden, CT, U.S.A.) and washed three times with 1 ml of ice cold 50 mM Tris-HCl pH 7.4 prior to scintillation counting on a Packard Top Count. Non specific binding was determined in the presence of 10 µM GTPγS.

The data of dose-response experiments were analyzed using program ALLFIT, to compute the EC₅₀ in the absence and presence of the various concentrations of antagonist.³⁸⁾

Aknowlegments We wish to thank Dr. Luciana Turchetto for mass spectra, Mr. Antonino Puccio and Mr. Leo Zanitti for technical assistance. Moreover we express our thanks to Prof. H. D. Höltje and to Prof. H. Jiang and Prof. X. Luo for kindly providing the NOP receptor 3D models.
