Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

KEYWORDS. Metabotropic glutamate receptor subtype 2 (mGlu₂), negative allosteric modulator (NAM), major depressive disorder (MDD), treatment-resistant depression (TRD), Alzheimer's disease

ABSTRACT. Both orthosteric and allosteric antagonists of the group II metabotropic glutamate receptors (mGlus) have been used to establish a link between mGlu_{2/3} inhibition and a variety of CNS diseases and disorders. Though these tools typically have good selectivity for mGlu_{2/3}

versus the remaining six members of the mGlu family, compounds that are selective for only one of the individual group II mGlus have proved elusive. Herein we report on the discovery of a potent and highly selective mGlu₂ negative allosteric modulator **58** (VU6001192) from a series of 4-oxo-1-aryl-1,4-dihydroquinoline-3-carboxamides. The concept for the design of this series centered on morphing a quinoline series recently disclosed in the patent literature into a chemotype previously used for the preparation of muscarinic acetylcholine receptor subtype 1 positive allosteric modulators. Compound **58** exhibits a favorable profile and will be a useful tool for understanding the biological implications of selective inhibition of mGlu₂ in the CNS.

INTRODUCTION

Glutamate (L-glutamic acid) is the major excitatory neurotransmitter in the mammalian central nervous system (CNS) and exerts its effects through both ionotropic and metabotropic glutamate receptors (mGlus). The mGlus belong to family C of the G-protein-coupled receptors (GPCRs) and are characterized by a seven transmembrane (7TM) α -helical domain connected via a cysteine rich-region to a large bi-lobed extracellular amino-terminal domain. The orthosteric binding site is found within this amino-terminal domain for each of the eight members of the mGlu family. The mGlus are further categorized into three groups according to their homology, preferred signal transduction mechanisms, and pharmacology. The group I mGlus (mGlu₁ and mGlu₅) are primarily located post-synaptically in neurons and coupled via G_q to the activation of phospholipase C, which leads to the elevation of intracellular calcium and activation of protein kinase C (PKC). On the other hand, group II mGlus (mGlu₂ and mGlu₃) and group III mGlus (mGlu₄, mGlu₆, mGlu₇ and mGlu₈) are primarily located pre-synaptically and are coupled via G_{i0} to the inhibition of adenylyl cyclase activity.¹⁻³ The expression of the group

Journal of Medicinal Chemistry

II mGlus is wide throughout the CNS; moreover, both are found in brain regions associated with emotional states such as the amygdala, hippocampus, and prefrontal cortex.^{4,5}

With multiple compounds having advanced into clinical trials in schizophrenic patients, the design of selective and drug-like positive allosteric modulators (PAMs) of mGlu₂ is significantly more advanced than complementary research directed toward selective negative allosteric modulators (NAMs) of the same receptor.⁶ Still, the literature contains multiple examples of highly optimized orthosteric antagonists and NAMs of the group II mGlus. Though these compounds typically possess good levels of selectivity against the other members of the mGlu family, they lack appreciable selectivity between mGlu₂ and mGlu₃.⁷ Consequently, much has been learned regarding the potential utility of group II mGlu inhibition through the use of these tools in animal models of various CNS disorders. The bulk of such studies have employed the two orthosteric antagonists 1 (LY341495)⁸ and 2 (MGS0039)⁹ (Figure 1). Specifically, potential therapeutic applications of group II mGlu antagonists have been established in obsessivecompulsive disorder (OCD).^{10,11} anxiety.¹² cognition.¹³ and Alzheimer's disease.¹⁴⁻¹⁶ Additionally, substantial work with these compounds has been directed toward establishing a role for mGlu_{2/3} antagonists as novel antidepressants.^{9,10,12,17–22} Perhaps most intriguing are studies demonstrating efficacy in animal models of treatment-resistant depression (TRD)²³ and anhedonia.24

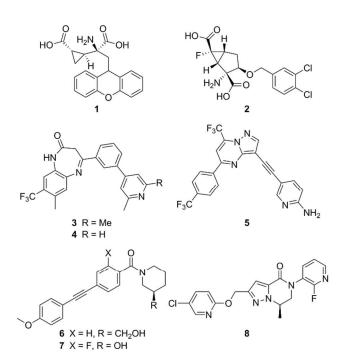

Figure 1. mGlu_{2/3} orthosteric antagonist tools **1** and **2**, mGlu_{2/3} NAM tools **3** and **4**, Roche mGlu_{2/3} NAM clinical compound **5**, first-generation selective mGlu₃ NAMs **6** and **7**, and mGlu₃ NAM *in vivo* tool **8**.

Reports of *in vivo* studies with mGlu_{2/3} NAMs are less prevalent; yet, two related compounds from a series of 4-aryl-1,3-dihydro-2*H*-benzo[*b*][1,4]diazepin-2-ones, **3** (RO4491533)²⁵ and **4** (RO4432717)^{26,27} (Figure 1), are worth noting. Studies in rodent models of depression^{25,28} and cognition^{27,29,30} with these tools have been disclosed and show similar results as those observed with mGlu_{2/3} orthosteric antagonists. Additionally, another structurally distinct mGlu_{2/3} NAM, **5** (decoglurant, RO4995819)³¹ from Roche (Figure 1), advanced into a phase II trial in patients with major depressive disorder (MDD) (NCT01457677).³² Thus, the evidence for a therapeutic application with mGlu_{2/3} antagonists is compelling; however, further elucidation is required regarding the individual importance of mGlu₂ and mGlu₃ in these various disorders. As such, we have been pursuing the design of selective antagonists of each receptor for use as *in vivo* tools. Page 5 of 59

Journal of Medicinal Chemistry

Our initial success came in the design of selective mGlu₃ NAMs from a series of 1,2diphenylethyne compounds represented by tool compounds **6** (VU0463597, ML289)³³ and **7** (VU0469942, ML337)^{34,35} (Figure 1). More recently we reported on another mGlu₃ NAM, **8** (VU0650786),³⁶ that is a superior *in vivo* tool and has demonstrated efficacy in rodent models of anxiety/OCD and depression.³⁶ Having selective mGlu₃ NAMs from multiple chemotypes in hand, we sought strategies for the design of selective mGlu₂ NAMs for the purpose of thoroughly evaluating the therapeutic potential of each individual target. Our first successful execution of such a strategy is described in this manuscript.

RESULTS AND DISCUSSION

Scaffold Design. In our search for new scaffolds suitable for the design of selective mGlu₂ NAMs, we were intrigued by a set of quinoline-2-carboxamide compounds **9** developed at Merck and disclosed in the patent literature (Figure 2).^{7,37} A survey of the functional mGlu₂ NAM activity presented in this application showed substantial tolerance for functional diversity at the 7-position with a variety of linkers connected to a number of unsaturated and saturated ring systems (**A**). The 4-position demonstrated a preference for aryl and heteroaryl rings (**B**), and a primary amide was preferred over a nitrile at the 2-position. We prepared an exemplar compound **10** and tested it in our own cell-based functional assays for mGlu₂ and mGlu₃.³⁵ These fluorescence-based assays measure calcium mobilization induced by receptor activation in a cell line stably expressing either rat mGlu₂ or rat mGlu₃ along with the promiscuous G-protein G_{α15} and are capable of detecting agonists, PAMs, and NAMs. Compound **10** exhibited potent NAM activity at mGlu₂ and no evidence of mGlu₃ activity up to the highest concentration tested (30 µM). The quinoline-2-carboxamide mGlu₂ NAMs were reminiscent of another series of allosteric

modulators developed at Merck, the 4-oxo-1,4-dihydroquinoline-3-carboxylic acid muscarinic acetylcholine receptor subtype 1 (M_1) PAMs **11**.³⁸⁻⁴⁰ Our hypothesis was that a new mGlu₂ NAM scaffold **12** might be obtained within a 4-oxo-1,4-dihydroquinoline series by appending appropriately linked groups (**A**) at the 6-position and installing *N*-aryl rings (**B**) at the 1-position in the context of a primary amide at the 3-position. In addition, the extensive M_1 PAM SAR already developed in this chemotype indicated that such changes would not be favorable for that target.

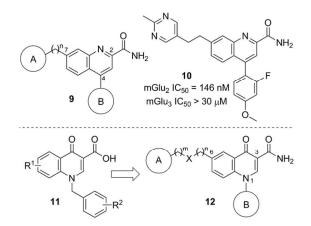

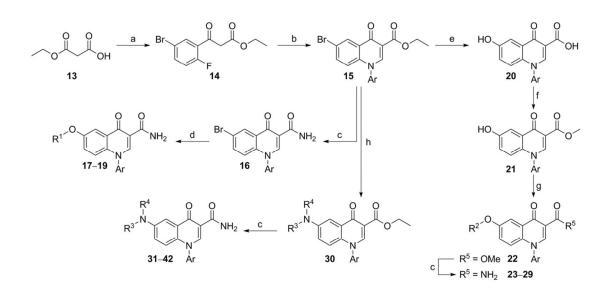

Figure 2. Merck quinoline-2-carboxamide mGlu₂ NAM scaffold **9** and representative compound **10**; Merck 4-oxo-1,4-dihydroquinoline-3-carboxylic acid M₁ PAM scaffold **11**; Proposed 4-oxo-1-aryl-1,4-dihydroquinoline-3-carboxamide mGlu₂ NAM scaffold **12**.

Synthesis of Compounds. It was envisioned that a number of interesting analogs could be prepared from versatile 6-bromo intermediate 15 (Scheme 1). The synthesis began with commercially available acid 13. Treatment of 13 with two equivalents of butyl lithium followed by addition of 5-bromo-2-fluoro-benzoyl chloride provided β -ketoester 14. Reaction of 14 with *N*,*N*-dimethylformamide dimethyl acetal followed by a suitable aryl amine under microwave

heating afforded the desired intermediate 15. Compound 15 could be converted to primary amide 16 through heating in ammonia in methanol under microwave irradiation to give 16. Where possible. 16 was used as a common intermediate: however, certain transformations proved incompatible with the primary amide functional group and necessitated the use of ester 15 with subsequent conversion to the primary amide at a later stage. Reaction of 16 with commercially available aryl alcohols (R¹OH) in the presence of copper (I) iodide and dimethylglycine provided aryl ether analogs 17-19 (Table 1). For synthesis of ethers 23-29 (Table 1), conversion of bromide 15 to alcohol 20 was accomplished with a palladium catalyzed hydroxylation.⁴¹ Acid 20 was converted to methyl ester 21 via a Fischer esterification. A Mitsunobu coupling⁴² with commercial alcohols (R²OH) was employed for installation of the various 6-substituted ethers to afford 22. Conversion of the ester moieties to the corresponding primary amides to yield 23–29 was carried out as described previously. Finally, the synthesis of amine analogs **31–42** (Table 2) was accomplished by first reacting bromide 15 with commercially available amines in a Buchwald-Hartwig amination reaction⁴³ to yield **30**. Conversion of **30** to analogs **31–42** was carried out as described previously.

Scheme 1. Synthesis of 6-heteroatom linked analogs^a

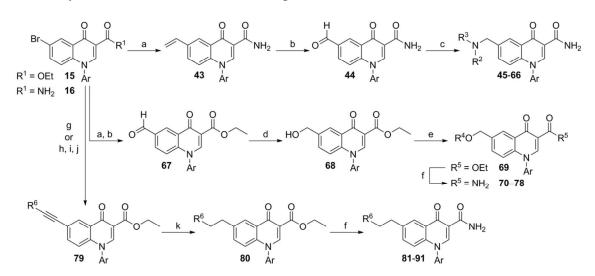

^{*a*} Reagents and conditions: (a) *n*-BuLi, 2,2'-bipyridyl, -30 °C to -5 °C, then 5-bromo-2-fluorobenzoyl chloride, -78 °C to -30 °C, 67%; (b) *N*,*N*-dimethylformamide dimethyl acetal, DMF, microwave, 120 °C, 15 min, then ArNH₂, microwave, 150 °C, 20 min, 60–98%; (c) 7N NH₃ in MeOH, microwave, 150 °C, 60 min, 29–99%; (d) R¹OH, CuI, Cs₂CO₃, Me₂NCH₂CO₂H, microwave, 150 °C, 15 min, 26–56% (e) KOH, Pd₂(dba)₃, *t*-BuXphos, dioxane, H₂O, microwave, 150 °C, 15 min, 99%; (f) MeOH, con. H₂SO₄, reflux, 74%; (g) R²OH, PPh₃, D^tBAD, THF, 40– 98%; (h) HNR³R⁴, Pd₂(dba)₃, Xantphos, Cs₂CO₃, PhMe, 110 °C, 8–54%.

In addition to the 6-heteroatom linked analogs, 6-carbon linked compounds were prepared from intermediates **15** and **16** (Scheme 2). Methylene-linked tertiary amine analogs **45–66** (Tables 3 and 4) were accessed through bromide **16**, which was first converted to vinyl intermediate **43** via a Suzuki coupling with potassium vinyltrifluoroborate.⁴⁴ Dihydroxylation of the olefin and subsequent *in situ* periodate cleavage of the resultant diol gave aldehyde **44**. Analogs **45–66** were then prepared through reductive aminations with **44** and commercially available secondary amines (HNR²R³). For preparation of methyleneoxy linked analogs **70–78** (Table 5), bromide **15** was converted to aldehyde **67** via an analogous vinylation,

dihydroxylation, and periodate cleavage as described above. Sodium borohydride reduction of **67** gave primary alcohol **68**, which was reacted in a Mitsunobu coupling⁴² with commercial alcohols (R⁴OH) to give ether intermediate **69**. Conversion of the ester moieties to the corresponding primary amides to yield **70–78** was carried out as described previously. Ethylene linked analogs **81–91** (Table 6 and Table 7) were also prepared from bromide **15** through initial preparation of alkynes **79**. Two methods were employed for preparation of these alkyne intermediates **79**, each relying on Sonogashira couplings⁴⁵ with bromide **15**. A coupling with **15** and a terminal alkyne (R⁶CCH) gave **79** directly. Alternatively, a coupling with trimethylsilylacetylene followed by fluoride mediated silyl cleavage gave a 6-alkyne intermediate that was coupled to an aryl bromide (R⁶Br) to afford **79**. A palladium catalyzed hydrogenation of the alkyne moiety provided **80**, which was reacted with ammonia as described previously to yield the target compounds **81–91**.

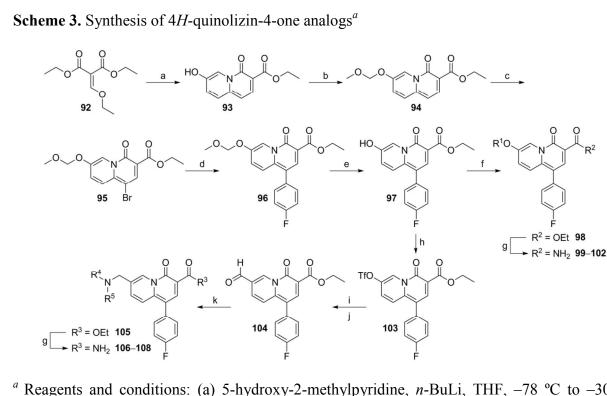

Scheme 2. Synthesis of 6-carbon linked analogs^a

^{*a*} Reagents and conditions: (a) H₂CCHBF₃K, Pd(dppf)·CH₂Cl₂, NEt₃, *n*-propanol, 100 °C, 75–100%; (b) OsO₄, NMO, acetone, H₂O, then NaIO₄, 91–99%; (c) HNR²R³, NaBH(OAc)₃, AcOH,

CH₂Cl₂, 7–81%; (d) NaBH₄, EtOH, 0 °C, 36–57%; (e) R⁴OH, PPh₃, D^tBAD, THF, 14–98%; (f) 7N NH₃ in MeOH, microwave, 150 °C, 15 min, 10–94%; (g) R⁶CCH, PdCl₂(PPh₃)₂, CuI, NEt₃, DMF, microwave, 150 °C, 15 min, 23–54%; (h) Me₃SiCCH, PdCl₂(PPh₃)₂, CuI, NEt₃, DMF, microwave, 150 °C, 15 min, 83%; (i) TBAF, THF, 70%; (j) R⁶Br, PdCl₂(PPh₃)₂, CuI, NEt₃, DMF, microwave, 150 °C, 15 min, 21–47%; (k) 10% Pd/C, MeOH, H₂ (1 atm), 63–99%.

In the case of the aforementioned 4-oxo-1.4-dihydroquinoline-3-carboxylic acid M_1 PAM scaffold, Merck has also shown that a 4H-quinolizin-4-one functioned as an effective bioisostere for the core of the chemotype.⁴⁶⁻⁴⁸ As such, we decided to prepare analogs with this core to evaluate its potential as an mGlu₂ NAM scaffold as well (Scheme 3). The synthesis began with lithiation of 5-hydroxy-2-methylpyridine and subsequent in situ reaction with commercially available diethyl 2-(ethoxymethylene)malonate 92 to give 7-hydroxy-4-oxo-4H-quinolizine 93. The alcohol was protected as its methoxymethyl ether 94, which was then selectively brominated at the 1-position to afford 95. A Suzuki coupling with 4-fluorophenylboronic acid provided intermediate 96. Acidic cleavage of the protecting group and simple filtration of the precipitated product gave 97, which served as the key intermediate for the synthesis of analogs. Ether compounds **99–102** (Table 8) were prepared via Mitsunobu coupling⁴² with commercial alcohols $(R^{1}OH)$ to yield 98, which was converted to primary amides 99–102 as described above. Intermediate 97 was also converted to the corresponding triflate 103, which was subjected to an analogous vinylation, dihydroxylation, and periodate cleavage as described previously to afford aldehyde 104. Finally, conversion of 104 to amines 105 and ultimately final compounds 106–108 followed methods outlined herein above.

^{*a*} Reagents and conditions: (a) 5-hydroxy-2-methylpyridine, *n*-BuLi, THF, -78 °C to -30 °C, 57%; (b) CH₃OCH₂Cl, DIEA, CH₂Cl₂, 0 °C to r.t., 96%; (c) NBS, CHCl₃, 0 °C to r.t., 96%; (d) 4-fluorophenylboronic acid, Pd(dppf)·CH₂Cl₂, 1M aq. Na₂CO₃, DME, 90 °C, 94%; (e) pTSA·H₂O, EtOH, DCE, 80 °C, 66%; (f) R¹OH, PPh₃, D^tBAD, THF, 0 °C to 45 °C, 38–82%; (g) 7N NH₃ in MeOH, microwave, 150 °C, 2.0–3.0 h, 26–90%; (h) PhN(SO₂CF₃)₂, NEt₃, CH₂Cl₂, 0 °C, 96%; (i) H₂CCHBF₃K, Pd(dppf)·CH₂Cl₂, NEt₃, *n*-propanol, 90 °C, 96%; (j) OsO₄, NMO, THF, H₂O, then NaIO₄, 70%; (k) HNR⁴R⁵, NaBH(OAc)₃, AcOH, CH₂Cl₂, 27–67%.

mGlu₂ NAM Activity and Preliminary DMPK SAR. As new analogs were evaluated for potency in our functional mGlu₂ assay, interesting compounds were further assessed in our frontline *in vitro* drug metabolism and pharmacokinetics (DMPK) assays. Specifically, metabolic stability was determined by measuring the intrinsic clearance of the compound when incubated with rat liver microsomes (RLM).⁴⁹ The intrinsic clearance obtained was used to calculate a

predicted hepatic clearance, and compounds were binned accordingly into low ($< \frac{1}{3}$ hepatic blood flow), moderate ($\frac{1}{3}$ to $\frac{2}{3}$ hepatic blood flow) and high (> $\frac{2}{3}$ hepatic blood flow) groups. The extent to which the compounds were bound to rat plasma was also measured.⁵⁰ We also calculated the lipophilicity of new analogs and attempted to assess the efficiency of the structural modifications being tested.⁵¹ Much of the SAR work was conducted in the context of a 4fluorophenyl ring at the 1-position of the scaffold as this was a group with good potency in the quinoline series, and it was likely to be somewhat metabolically stable. As expected, the mGlu₂ NAM SAR with the new 4-oxo-1,4-dihydroquinoline ether analogs showed a good deal of tolerance at the 6-position (Table 1). The ethers with directly linked heteroaryl rings (17–19) were among the least active in this set; however, in vitro DMPK was benchmarked. The fraction unbound in rat plasma with 17 was 0.083, and the predicted hepatic clearance was moderate. The remaining analogs 23-29 possessed a single sp³ hybridized carbon between the 6-position ether oxygen and the heteroaryl ring (A). This feature generally improved $mGlu_2$ NAM activity. The methyl groups of analogs 24 and 25 both provided small boosts of potency relative to unsubstituted 3-pyridyl ring 23. Analogous 4-pyridyl methyl analogs 27 and 28 were approximately two-fold more potent than unsubstituted comparator 26. Pyrimidine analog 29 was less potent than 3-pyridyl analog 24; however installation of this nitrogen atom reduced lipophilicity, and the ligand-lipophilicity efficiency (LLE) of 29 indicated that this 2methylpyrimidin-5-yl functional group was worthy of continued evaluation in other analogs. The compounds examined (24, 25, 27, 28) in our *in vitro* DMPK assays again had fraction unbound in rat plasma similar to 17, but only 24 had moderate predicted hepatic clearance with the remaining analogs having CL_{hep} values near liver blood flow.

4-Oxo-1,4-dihydroquinoline amine analogs further illustrated the tolerance for variation at the 6-position (Table 2). Additionally, many of these analogs exhibited superior $mGlu_2$ NAM potency compared to the ether analogs discussed above. Simple alkylation of the nitrogen linker generally had minimal impact on mGlu₂ NAM activity as evidenced by comparing secondary amine analogs 31 and 34 to their tertiary amine comparators 32, 35, and 36; however, in each case, the tertiary amine analogs exhibited a higher predicted hepatic clearance, possibly due to Ndealkylation. In the case of analogs with the ring (A) directly attached to the nitrogen linker, the 3-pyridyl ring (32) exhibited superior mGlu₂ NAM activity compared to the 4-pyridyl ring (33). On the other hand, the difference in potency was minimal when a methylene (35 and 37) or ethylene spacer (40 and 41) was inserted between the nitrogen atom and the ring (A). Combining

the methylene spacer with the 2-methylpyrimidin-5-yl ring (**38**) provided the most potent compound in this set. The fraction unbound was considerably higher with **38** relative to other similar analogs (**35** and **37**), and the predicted hepatic clearance, though still high, was less than the majority of the other analogs in this set. Though analogs **39** and **42** were not among the most potent amine analogs, these derivatives demonstrated that saturated heteroaryl rings were also tolerated at the 6-position of the chemotype.

Having observed that aromatic rings were not required at the 6-position, we were interested to evaluate the numerous methylene amine analogs prepared at that position. Several of these

analogs were simple tertiary amines without additional heteroatoms in the ring system (Table 3). The mGlu₂ NAM activity observed with these compounds was generally more dependent on minor structural changes than had been observed with previous compounds. For example, difluorocyclobutylamine **45** was approximately 5-fold more potent than cyclopentylamine **46**, and difluropyrrolidine **48** was approximately 8-fold more potent than difluoroazaspiroheptane **47**. Likewise, though unsubstituted piperidine **49** was only a weak mGlu₂ NAM, inhibiting the glutamate response only at the highest concentration (30 μ M), further substitution of the ring with a variety of moieties enhanced potency (**50–54**). Three analogs (**45**, **48**, and **54**) were evaluated in our *in vitro* DMPK assays, and while the protein binding results were encouraging with more than ten percent unbound in each case, predicted hepatic clearance remained high (>48 mL/min/kg).

In addition to the simple tertiary amines highlighted above, we also prepared a number of analogs with heterocyclic amines (Table 4). Substituted morpholine analogs **55–58** were potent mGlu₂ NAMs with the dimethyl substituted analogs **57** and **58** offering potency superior to monomethyl analogs **55** and **56**. Particularly encouraging was analog **58**, which was predicted to be a low-moderate clearance compound in rats and was approximately 30% unbound in rat plasma. On the other hand, thiomorpholine **59** exhibited high clearance *in vitro*, and thiomorpholine 1,1-dioxide **60** showed reduced potency. We also prepared several analogs were moderate to weak mGlu₂ NAMs, 1,4-thiazepane **65** was quite potent. Unfortunately, **65** was highly cleared *in vitro*; however, oxidation of the sulfur atom was a likely metabolic soft-spot as clearance with 1,4-thiazepane 1,1-dioxide **66** was substantially reduced.

Turning our attention to the 6-aryloxymethyl ether analogs **70–78** uncovered several additional compounds with good mGlu₂ NAM potency (Table 5). Several 3-pyridyl derivatives (**70–74**) were prepared, and 6-methyl derivative **72** and 6-chloro derivative **73** exhibited good potency. Interestingly, a trifluoromethyl group (**74**) did not function as an adequate alternative at this position. The pyridyl derivatives (**75–77**) demonstrated more modest differences in mGlu₂ NAM activity, and in this case the trifluoromethyl (**77**) was only slightly less potent than its corresponding methyl comparator (**76**). Fraction unbound with these pyridyl analogs was in line with other similar analogs (see Table 1), and predicted clearance ranged from moderate (**72** and **76**) to high (**73** and **75**). Once again, we installed a 2-methylpyrimidin-5-yl ring (**78**) and observed positive results. Specifically, not only was **78** a potent mGlu₂ NAM, it exhibited more than 10% fraction unbound in rat plasma and a low predicted clearance in rat liver microsomes.

Finally, examination of 6-ethylene linked analogs 81–87 yielded a range of results (Table 6). Unsubstituted phenyl analog 81 demonstrated weak mGlu₂ NAM activity; however, modification of the aromatic ring (A) to pyridine (82 and 84) improved potency approximately 15-fold. Unfortunately, both 82 and 84 were highly cleared in vitro. Substitution of 4-pyridyl analog 82 with a trifluoromethyl group (83) modestly enhanced potency but without reducing clearance. Substitution of 3-pyridyl analog 84 with trifluoromethyl (85) and fluorine (86) was unfavorable for mGlu₂ NAM activity. Again the 2-methylpyrimidin-5-yl ring (87) proved an attractive moiety, having demonstrated the most potent activity and highest fraction unbound in this set of analogs. Also, although predicted hepatic clearance for 87 remained on the high end, it was improved relative to other analogs in this class (82–84).

Having developed substantial SAR at the 6-position of the chemotype, we wanted to conduct limited exploration of another area as well. We chose ethylene linked analog 87 as a useful comparator given its overall profile. As such, additional analogs of 87 with alternative aromatic rings (B) to the 4-fluorophenyl ring were prepared and tested (Table 7). Replacement of the 4fluoro group (87) with a 4-methoxy group (88) improved mGlu₂ NAM potency slightly, but the predicted hepatic clearance of 88 remained high. Since methoxy groups increase electron density on the ring, fluorinated analogs 89 and 90 were prepared; however, these modifications failed to improve metabolic stability. It was encouraging to see that the 4-fluorophenyl ring could be replaced altogether with a 3-methylisothiazol-5-yl ring (91). Analog 91 demonstrated a 2-fold drop in potency relative to 87; yet, this modification was considered efficient by the LLE quotient as it was a less lipophilic compound. Of note, 91 had an increased fraction unbound and a marginally and perhaps insignificantly lower predicted hepatic clearance than 87. Continued exploration of this region (B) of the scaffold is clearly worthwhile; however, at this point, we decided to more thoroughly profile some of the promising analogs discovered thus far to evaluate the full potential of the 4-oxo-1-aryl-1,4-dihydroquinoline-3-carboxamides as a lead series for the discovery of drug-like mGlu₂ NAMs.

Prior to discussing the results of extended profiling of select 4-oxo-1-aryl-1,4dihydroquinolines, it is worth briefly discussing the results obtained with the 4*H*-quinolizin-4one analogs (Table 8). Whether in the case of the ether analogs (**99–102**) or methylene amine analogs (**106–108**), mGlu₂ NAM potency was consistently weak. In fact, when compared to their analogous compounds in the 4-oxo-1-aryl-1,4-dihydroquinoline series, these analogs were notably less potent in each case. These results are important because it illustrates that these two cores are not uniformly interchangeable. Moreover, it provides another example of the subtleties of SAR often seen in the design of allosteric modulators of class C GPCRs.^{52–54}

Extended Characterization of Selected Analogs. In choosing the initial compounds for more in depth evaluation, we sought molecules with both promising mGlu₂ NAM potency and *in vitro* DMPK profiles while also desiring some structural diversity at the 6-position substituent. As such, we selected ether 17, amine 34, methylene amines 54 and 58, and ethylene linked analog 87 for further profiling (Table 9). Since the potential therapeutic applications for an mGlu₂ NAM are in the area of CNS disorders, blood-brain barrier (BBB) penetration seemed a logical next step for evaluation in this new series. It should be noted that the fraction unbound in rat plasma ranged from 0.083 to 0.306 with these compounds; thus, consideration of unbound fraction alongside potency and CNS exposure is required to fully evaluate these compounds. Toward this end, we employed rat cassette pharmacokinetics (PK) tissue distribution studies using intravenous (IV) dosing and single time point analysis.⁵⁵ Such an approach has repeatedly proven a rapid and cost-effective mechanism for preliminary assessment of BBB penetration. In addition to the already measured protein binding in rat plasma, the protein binding of these compounds in rat brain homogenates was also assessed. Unfortunately, the observed brain to plasma ratio (K_p) for each compound was low, ranging from 0.04 (34) to 0.36 (54). Calculation of the unbound brain to unbound plasma ratio ($K_{p,uu}$) gave values that were all below 0.25,

indicating possible transporter effects.⁵⁶ Thus, analogs **58** and **87** were selected for permeability studies in Madin-Darby canine kidney (MDCK) cells transfected with the human MDR1 gene to assess potential P-glycoprotein (P-gp) mediated efflux.⁵⁷ Both compounds demonstrated substantial efflux with ratios of 52 and 44, respectively. While it was disappointing to learn that this scaffold appeared to suffer from P-gp-mediated efflux, the absolute CNS concentrations observed with 58 and its other properties raised the possibility that it might still be a valuable tool.

Further profiling of compound 58 (VU6001192) began with determination of its full selectivity versus other members of the mGlu family. Selectivity versus fellow group II receptor subtype, mGlu₃, was particularly critical to assess. Gratifyingly, we evaluated the selectivity of 58 versus rat mGlu₃ using 10 point concentration-response curve (CRC) analysis in the presence of an EC_{80} concentration of glutamate, and **58** was inactive up to the highest concentration tested

Journal of Medicinal Chemistry

(30 μ M). For evaluation of selectivity versus other members of the mGlu family, the effect of 10 μ M **58** on the orthosteric agonist CRC was measured in fold-shift experiments.^{58,59} Fortunately, no activity at the other mGlus was noted in these assays. Because the genesis for the 4-oxo-1-aryl-1,4-dihydroquinoline chemotype as a mGlu₂ NAM scaffold was inspired in part by a known M₁ PAM scaffold, we also evaluated **58** in our human M₁ functional assay⁶⁰ and observed no activity up to the highest concentration tested (30 μ M). Ancillary pharmacology was evaluated through screening **58** at 10 μ M in a commercially available radioligand binding assay panel of 68 clinically relevant GPCRs, ion channels, kinases, and transporters,⁶¹ and no significant responses were noted.⁶²

Having established the excellent selectivity profile of **58**, we progressed the compound to additional and more definitive PK studies in both rats and mice (Table 10).⁶³ In spite of its predicted low-moderate clearance, a time course study using IV dosing showed **58** to be a high clearance compound; however, the volume of distribution at steady state (V_{SS}) was high and the half-life was approximately 2 hours. Thus, intraperitoneal (IP) dosing was chosen as a route that was both convenient for future use in behavioral models and had the likelihood of providing superior exposure to oral dosing. An IP tissue distribution study in rats at 30 mg/kg gave K_p and K_{p,uu} values similar to those observed previously; yet, we observed a brain concentration of 760 nM, which translates to an unbound brain concentration of 145 nM and is very near the functional mGlu₂ IC₅₀ (207 nM). An analogous study in mice at the same dose gave similar results with a brain concentration of 716 nM, which translates to an unbound brain concentration of 184 nM. Finally, to verify the role of P-gp *in vivo*, we repeated the study in mice with the modification of pre-treating the animals with the known P-gp inhibitor **109** (elacridar).⁶⁴ The

impact of this modification was profound as the exposure of **58** in the brain was increased more than 6-fold without impacting the systemic exposure in plasma.

CONCLUSION

A potent and highly selective $mGlu_2$ NAM tool compound **58** was discovered through scaffold hopping a series in the patent literature and recognizing the possibility that an established M₁ PAM series might function as a viable chemotype for new analog design. Diverse functional groups were tolerated at the 6-position of the new chemotype, and limited work established the potential for further modifications at the 1-position. While the utility of the

compounds tested thus far is hampered by P-gp mediated efflux that limits CNS exposure, the overall profile of **58** remains interesting. The compound exhibits an unbound fraction of 25–30% in rodent brain homogenates, and a dose of 30 mg/kg using IP dosing produces unbound brain concentrations near the functional mGlu₂ IC₅₀. Conceivably, higher doses could be employed in order to reach pharmacologically relevant concentrations in the CNS. Perhaps more attractive is the fact that pre-treatment with a commercially available P-gp inhibitor boosts the unbound brain exposure of **58** to more than 5-fold the mGlu₂ IC₅₀ at the same dose. The study of **58** in behavioral models relevant to mGlu₂ inhibition is planned and will be the subject of future communications.

EXPERIMENTAL SECTION

The synthesis of compound **58** and its associated intermediates is described below for convenience. Synthetic details for other compounds can be found in the Supporting Information.

Ethyl 3-(5-bromo-2-fluorophenyl)-3-oxopropanoate (14). 3-Ethoxy-3-oxo-propanoic acid 13 (2.16 mL, 18.3 mmol, 2.00 eq) was dissolved in THF (91 mL) in an oven dried round-bottom flask and 2,2'-bipyridyl (8.00 mg, 0.0512 mmol, 0.0056 eq) was added as an indicator. The reaction was cooled to -30 °C and *n*-butyllithium (1.6 M in hexanes) (29.0 mL, 45.6 mmol, 4.00 eq) was added dropwise over 20 minutes. Upon final addition the reaction turned red at which point it was allowed to warm to -5 °C. The reaction was allowed to stir at -5 °C for 15 minutes, during which time the red color began to dissipate. Enough *n*-butyllithium was added to allow the red color to persist. The reaction was then cooled to -78 °C and 5-bromo-2-fluoro-benzoyl chloride (2.17 g, 9.14 mmol, 1.00 eq) was added dropwise as a solution in THF (6.9 mL). The reaction was allowed to stir at -78 °C for 30 minutes and then allowed to warm to -30 °C and

stirred for an additional 30 minutes. The reaction was poured onto ice-cold 1N HCl (92 mL) and the mixture was extracted with ethyl acetate (1x) and DCM (2x). The combined organics were dried (MgSO₄), filtered and concentrated *in vacuo*. Purification by flash chromatography on silica gel afforded 1.78 g (67%) of the title compound as an off-white solid. ¹H NMR (400 MHz, DMSO-*d*₆): δ = 7.97 (dd, *J* = 6.5, 2.6 Hz, 1H), 7.91-7.86 (m, 1H), 7.40-7.34 (m, 1H), 4.13-4.07 (m, 4H), 1.15 ppm (t, *J* = 7.1 Hz, 3H). ¹³C NMR (100 MHz, DMSO-*d*₆): δ = 189.68 (d, *J*(C,F) = 3.2 Hz), 167.09, 160.26 (d, *J*(C,F) = 255 Hz), 138.09 (d, *J*(C,F) = 9.5 Hz), 132.49 (d, *J*(C,F) = 2.2 Hz), 126.16 (d, *J*(C,F) = 13.3 Hz), 119.51 (d, *J*(C,F) = 25.1 Hz), 116.64, 60.71, 48.81, 13.92 ppm. HRMS (ESI): calculated for C₁₁H₁₀BrFO₃ [M]: 287.9797; found: 287.9794. LCMS R_T = 0.989 min, ES-MS *m/z* = 289.0 [M+H]⁺.

Ethyl 6-bromo-1-(4-fluorophenyl)-4-oxo-1,4-dihydroquinoline-3-carboxylate (15, where Ar

= 4-fluorophenyl). Compound **14** (2.87 g, 9.93 mmol, 1.00 eq) and *N*,*N*-dimethylformamide dimethyl acetal (1.87 mL, 14.9 mmol, 1.50 eq) were dissolved in DMF (33 mL) in a microwave vial and heated in a microwave reactor at 120 °C for 15 minutes. To this mixture was then added 4-fluoroaniline (1.41 mL, 14.9 mmol, 1.50 eq) and the reaction was heated in a microwave reactor at 150 °C for 20 minutes. The reaction mixture was diluted with ethyl acetate and washed with water (2x). The aqueous layers were back-extracted with ethyl acetate and the combined organics were dried (MgSO₄), filtered and concentrated *in vacuo*. Purification by flash chromatography on silica gel afforded 3.79 g (98%) of the title compound as yellow solid. ¹H NMR (400 MHz, DMSO-*d*₆) δ = 8.47 (s, 1H), 8.31 (d, *J* = 2.4 Hz, 1H), 7.81 (dd, *J* = 9.1, 2.4 Hz, 1H), 7.77-7.73 (m, 2H), 7.54-7.50 (m, 2H), 6.92 (d, *J* = 9.0 Hz, 1H), 4.20 (q, *J* = 7.1 Hz, 2H), 1.25 ppm (t, *J* = 7.1 Hz, 3H). ¹³C NMR (100 MHz, DMSO-*d*₆): δ = 171.80, 163.90, 162.43 (d, *J*(C,F) = 247.5 Hz), 149.02, 139.70, 136.38 (d, *J*(C,F) = 2.8 Hz), 135.37, 130.17 (d, *J*(C,F) = 9.0

Hz), 128.83, 128.15, 120.73, 118.06, 117.26 (d, J(C,F) = 23.2 Hz), 110.88, 60.04, 14.21 ppm. HRMS (ESI): calculated for C₁₈H₁₃BrFNO₃ [M]: 389.0063; found: 389.0062. LCMS R_T = 0.934 min, ES-MS m/z = 390.2 [M+H]⁺.

6-Bromo-1-(4-fluorophenyl)-4-oxo-1,4-dihydroquinoline-3-carboxamide (16, where Ar = 4-fluorophenyl). Ethyl 6-bromo-1-(4-fluorophenyl)-4-oxo-1,4-dihydroquinoline-3-carboxylate (1.00 g, 2.56 mmol, 1.00 eq) was suspended in 7N ammonia in methanol (30 mL) in a microwave vial and the reaction was heated in a microwave reactor at 150 °C for 60 minutes. The reaction was concentrated to afford 881 mg (95%) of the title compound as a brown solid that was used without further purification. ¹H NMR (400 MHz, DMSO-*d*₆) δ = 9.08 (d, *J* = 4.0 Hz, 1H), 8.57 (s, 1H), 8.43 (d, *J* = 2.4 Hz, 1H), 7.85 (dd, *J* = 9.1, 2.4 Hz, 1H), 7.77-7.73 (m, 2H), 7.66 (d, *J* = 4.1 Hz, 1H), 7.56-7.50 (m, 2H), 7.02 ppm (d, *J* = 9.1 Hz, 1H). ¹³C NMR (100 MHz, DMSO-*d*₆): δ = 174.64, 164.83, 162.46 (d, *J*(C,F) = 247.6 Hz), 148.42, 139.85, 136.50 (d, *J*(C,F) = 2.8 Hz), 135.66, 129.97 (d, *J*(C,F) = 9.3 Hz), 128.09, 128.07, 120.86, 118.19, 117.31 (d, *J*(C,F) = 23.3 Hz), 112.07 ppm. HRMS (ESI): calculated for C₁₆H₁₀BrFN₂O₂ [M]: 359.9910; found: 359.9909. LCMS R_T = 0.929 min, ES-MS *m*/*z* = 361.2 [M+H]⁺.

1-(4-Fluorophenyl)-4-oxo-6-vinyl-1,4-dihydroquinoline-3-carboxamide (43, where Ar = 4-fluorophenyl). To a solution of 6-bromo-1-(4-fluorophenyl)-4-oxo-1,4-dihydroquinoline-3-carboxamide (450 mg, 1.25 mmol, 1.0 eq), triethylamine (174 μ L, 1.25 mmol, 1.0 eq), and Pd(dppf)Cl₂·CH₂Cl₂ (18.2 mg, 0.025 mmol, 0.2 eq) in 1-propanol (8.3 mL) was added potassium vinyltrifluoroborate (200 mg, 1.5 mmol, 1.2 eq). The mixture was purged with argon and stirred at 100 °C for 16 hours. The reaction was filtered through Celite® and washed very well with a 5%MeOH in DCM solution. The filtrate was concentrated *in vacuo* to give 385 mg (100%) of the title compound, which was used without further purification. ¹H NMR (400 MHz, DMSO-

 d_6): $\delta = 9.23$ (d, J = 4.2 Hz, 1H), 8.55 (s, 1H), 8.36 (d, J = 1.6 Hz, 1H), 7.89 (dd, J = 1.8, 8.9 Hz, 1H), 7.79-7.75 (m, 2H), 7.64 (d, J = 4.2 Hz, 1H), 7.54 (t, J = 8.7 Hz, 2H), 7.03 (d, J = 8.8 Hz, 1H), 6.93 (q, J = 11, 6.6 Hz, 1H), 5.95 (d, J = 17.6 Hz, 1H), 5.39 ppm (d, J = 11 Hz, 1H). ¹³C NMR (100 MHz, DMSO- d_6): $\delta = 175.79$, 165.17, 162.36 (d, J(C,F) = 247.0 Hz), 147.77, 140.24, 136.74 (d, J(C,F) = 3.2 Hz), 135.38, 134.17, 130.1, 129.93 (d, J(C,F) = 9.0 Hz), 126.74, 123.72, 118.65, 117.35 (d, J(C,F) = 23.4 Hz), 115.9, 111.72 ppm. HRMS (ESI): calculated for $C_{18}H_{13}FN_2O_2$ [M]: 308.0961; found: 308.0964. LCMS $R_T = 0.922$ min, ES-MS m/z = 309.2 [M+H]⁺.

1-(4-Fluorophenyl)-6-formyl-4-oxo-1,4-dihydroquinoline-3-carboxamide (44, where Ar = 4fluorophenyl). To a solution of 1-(4-fluorophenyl)-4-oxo-6-vinyl-1,4-dihydroquinoline-3carboxamide (385 mg, 1.25 mmol, 1.0 eq) in 3:1 acetone/water (8 mL) was added N-oxide-4methylmorpholine (220 mg, 1.87 mmol, 1.5 eq) and osmium tetroxide (6.3 mg, 0.025 mmol, 0.02 eq). After the reaction stirred for one hour, sodium periodate (294 mg, 1.37 mmol, 1.1 eq) was added. After another two hours, the reaction was diluted with EtOAc and washed well with a 10% NaS₂O₃ solution. The organic layer was dried (MgSO₄), filtered and concentrated in vacuo to give 365 mg (94%) of the title compound that was used without further purification. ¹H NMR $(400 \text{ MHz}, \text{DMSO-}d_6): \delta = 10.17 \text{ (s, 1H)}, 9.10 \text{ (d, } J = 3.8 \text{ Hz}, 1\text{H)}, 8.93 \text{ (d, } J = 1.8 \text{ Hz}, 1\text{H)}, 8.62$ (s, 1H), 8.12 (dd, J = 1.8, 8.8 Hz, 1H), 7.82-7.78 (m, 2H), 7.74 (d, J = 3.8 Hz, 1H), 7.56 (t, J =8.8 Hz, 2H), 7.22 ppm (d, J = 8.8 Hz, 1H). ¹³C NMR (100 MHz, DMSO- d_6): $\delta = 192.23$, 175.88, 164.68, 162.49 (d, J(C,F) = 247 Hz), 149.06, 144.23, 136.61 (d, J(C,F) = 3.2 Hz), 132.48, 130.98, 130.41, 130.0 (d, J(C,F) = 9.3 Hz), 126.54, 119.46, 117.37 (d, J(C,F) = 23.3 Hz), 112.78 ppm. HRMS (ESI) calculated for C₁₇H₁₁FN₂O₃ [M]: 310.0754; found: 310.0757. LCMS $R_T = 0.732 \text{ min}$, ES-MS $m/z = 311.2 [M+H]^+$.

6-((cis-2,6-Dimethylmorpholino)methyl)-1-(4-fluorophenyl)-4-oxo-1,4-dihydroquinoline-3carboxamide (58). A solution of 1-(4-fluorophenyl)-6-formyl-4-oxo-1,4-dihydroquinoline-3carboxamide (580 mg, 1.87 mmol, 1.0 eq) in dichloromethane (1 mL), cis-2,6dimethylmorpholine (461 µL, 3.74 mmol, 2.0 eq), and acetic acid (268 µL, 4.67 mmol, 2.5 eq) was stirred for one hour. Sodium triacetoxyborohydride (594 mg, 2.80 mmol, 1.5 eg) was added. After 16 hours, the reaction was concentrated to dryness. Purification by reverse phase HPLC afforded 620 mg (81%) of the title compound as a white solid. ¹H NMR (400 MHz, DMSO- d_6) δ 9.23 (d, J = 4.4 Hz, 1H), 8.55 (s, 1H), 8.26 (d, J = 1.4 Hz, 1H), 7.77-7.73 (m, 2H), 7.65 (dd, J = 1.4 Hz, 7.85 (dd, J = 1.4 1.8, 8.7 Hz, 1H), 7.59 (d, J = 4.3 Hz, 1H), 7.52 (t, J = 8.7, 2H), 7.03 (d, J = 8.7, 1H), 3.57-3.52 (m, 4H), 2.65 (d, J = 10.7 Hz, 2H), 1.68 (t, J = 10.7 Hz, 2H), 1.01 ppm (d, J = 6.2 Hz, 6H). ¹³C NMR (100 MHz, DMSO- d_6): $\delta = 175.8$, 165.26, 162.36 (d, J(C,F) = 247 Hz), 147.78, 139.9, 136.82 (d, *J*(C,F) = 3.1 Hz), 135.26, 133.91, 129.98 (d, *J*(C,F) = 8.9 Hz), 126.41, 125.85, 118.26, 117.22 (d, J(C,F) = 23.0 Hz), 111.59, 70.97, 61.23, 58.81, 18.96 ppm. HRMS (ESI) calculated for C₂₃H₂₄FN₃O₃ [M]: 409.1802; found: 409.1804. LCMS $R_T = 0.644$ min, ES-MS m/z = 410.3 $[M+H]^+$.

Author Contributions

Drs. Emmitte and Lindsley directed and designed the chemistry. Dr. Felts, Ms. Smith, and Dr. Engers performed the medicinal chemistry. Drs. Conn and Niswender directed and designed the molecular pharmacology experiments. Dr. Rodriguez directed and performed molecular pharmacology experiments. Mr. Venable performed molecular pharmacology experiments. Dr. Daniels directed and designed the DMPK experiments. Drs. Locuson and Blobaum directed DMPK experiments and performed bioanalytical work. Mr. Morrison performed bioanalytical work. Mr. Chang performed *in vitro* DMPK work. Mr. Byers performed *in vivo* DMPK work.

Funding Source

This work was generously supported by the NIMH R01MH099269 (K.A.E) and U54MH084659 (C.W.L.).

ACKNOWLEDGMENTS

We gratefully acknowledge the generous support of the National Institute of Mental Health for the funding of this work, NIMH R01MH099269 (K.A.E) and U54MH084659 (C.W.L.).
