### Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

**Abstract**

6-Nitro-2,3-dihydroimidazo[2,1-*b*][1,3]oxazole derivatives were initially studied for tuberculosis within a backup program for the clinical trial agent pretomanid (PA-824). Phenotypic screening of representative examples against kinetoplastid diseases unexpectedly led to the identification of DNDI-VL-2098 as a potential first-in-class drug candidate for visceral leishmaniasis (VL). Additional work was then conducted to delineate its essential structural features, aiming to improve solubility and safety without compromising activity against VL. While the 4-nitroimidazole portion was specifically required, several modifications to the aryloxy side chain were well tolerated e.g., exchange of the linking oxygen for nitrogen (or piperazine), biaryl extension, and replacement of phenyl rings by pyridine. Several less lipophilic analogues displayed improved aqueous solubility, particularly at low pH, although stability towards liver microsomes was highly variable. Upon evaluation in a mouse model of acute *Leishmania donovani* infection, one phenylpyridine derivative (**37**) stood out, providing efficacy surpassing that of the original preclinical lead.

## INTRODUCTION

Neglected tropical diseases (NTDs) affect in excess of one billion people, predominantly in the most impoverished areas of the world, causing more than half a million deaths each year, as well as much physical suffering and social stigma.<sup>1,2</sup> Of the 17 major NTDs, the kinetoplastid parasite diseases visceral leishmaniasis (VL), Chagas disease, and human African trypanosomiasis (HAT) are considered amongst the most challenging, due to their high mortality rates and limited treatment options, with little economic incentive for this to change.<sup>2</sup> VL is caused by *Leishmania donovani* (*L. don*) and *Leishmania infantum* (*L. inf*), transmitted by female sand flies; these parasites first multiply inside host macrophages before spreading to and destroying other tissues (e.g., spleen, liver, and bone marrow).<sup>3,4</sup> Annual incidence of VL is now estimated at 300000, with infection occurring mainly in rural areas of East Africa, India, Bangladesh and Brazil. Most of the ~35000 deaths each year pass unrecognised, and in East Africa, lethal epidemics take place frequently.<sup>5</sup> However, the current treatments for VL are unsatisfactory.<sup>3,4</sup> Pentavalent antimonials have been the standard first-line remedy since the 1940s, but these are cardiotoxic and require painful parenteral administration over 1 month; drug resistance has now severely limited their utility in India. A less toxic liposomal form of the antifungal agent, amphotericin B (**1**; see Figure 1), has proven widely effective but is limited by high cost. The cheaper aminoglycoside antibiotic, paromomycin (**2**), has variable efficacy, both within and between regions. Finally, the alkyl phospholipid miltefosine (**3**), a long-acting anticancer drug repurposed for VL, is the sole oral agent; nevertheless, this also suffers from several disadvantages, including cost, teratogenicity, and treatment failures. Hence, there remains an urgent need for more effective, safe, and affordable oral treatments for VL. In the last decade of tuberculosis (TB) and NTD drug discovery, there has been major interest in exploiting potential development shortcuts, via the repurposing of approved drugs, rescue of “failed” clinical agents, or repositioning of

1  
2  
3 early or late stage drug candidates.<sup>6-8</sup> Indeed, for organizations such as the Global Alliance  
4 for TB Drug Development (TB Alliance) and the Drugs for Neglected Diseases *initiative*  
5 (DNDi), phenotypic screening is still viewed as a highly useful, cost-effective strategy to  
6 identify “low hanging fruit”.<sup>9-11</sup> Recent cooperation between these two organizations in this  
7 regard actually provided the foundation for this current study.<sup>12</sup>  
8  
9  
10  
11  
12

13  
14 In early collaborative work with TB Alliance (2005-6) we investigated<sup>13</sup> several  
15 nitroheterobicyclic ring analogues of the bio-reductive TB agent pretomanid (PA-824, **4**), now  
16 in phase III clinical evaluation.<sup>14</sup> However, our efforts in the known<sup>15</sup> 6-nitroimidazooxazole  
17 class were curbed following disclosure of the recently approved<sup>16</sup> MDR-TB drug delamanid  
18 (OPC-67683, **5**),<sup>17,18</sup> turning our focus for a backup toward the efficacious biaryl analogues  
19 of **4**.<sup>19-21</sup> Both **4** and **5** are activated by an intracellular deazaflavin dependent nitroreductase  
20 (Ddn) in *Mycobacterium tuberculosis* (*M. tb*), resulting in inhibition of cell wall synthesis as  
21 well as respiratory poisoning (via nitric oxide release).<sup>22</sup> This mode of action is distinct from  
22 the postulated *nucleophilic* nitro reduction (e.g., by thiolate) of other new nitroaromatic TB  
23 agents, such as PBTZ169 (**6**) and nitrobenzamides, to form reactive nitroso intermediates,  
24 which trigger suicide inhibition of an enzyme (DprE1) involved in cell wall biosynthesis.<sup>23,24</sup>

38 In late 2009, follow-up interest from DNDi in some promising antileishmanial screening  
39 data for several of our earlier nitroimidazole derivatives (above) then led to our nomination of  
40 three unoptimised racemic hits, including two from the most potent 6-nitroimidazooxazole  
41 class (**7** and **8**), for proof-of-concept *in vivo* assessment in a mouse model of VL. In parallel,  
42 taking into account the preliminary SAR findings, a further 72 compounds were screened  
43 against *L. don* in a macrophage-based luciferase assay at the Central Drug Research Institute  
44 (CDRI, India),<sup>25</sup> and 10 of these were later tested in the same mouse model. However, the  
45 outstanding *in vivo* efficacy of **7** was not surpassed by any of the other candidates, and  
46 following our synthesis of its enantiomers and ensuing head-to-head assessments of these, the

2  
3 *R* enantiomer **9** (DNDI-VL-2098)<sup>18</sup> was chosen for preclinical evaluation as a potential first-  
4 in-class drug candidate for VL.<sup>25,26</sup> In this report, we initially detail results relevant to the  
5 selection of **9**. We then describe the findings of more recent work aimed at discovering  
6 backups to **9** having an improved physicochemical/ pharmacological profile and better safety,  
7 providing wider SAR conclusions for the nitroimidazooxazole class against TB and three  
8 kinetoplastid NTDs, together with a first *in vivo* appraisal of the best new leads for VL.

## 17 CHEMISTRY

18  
19  
20 Several earlier investigators<sup>15,27</sup> prepared 6-nitro-2,3-dihydroimidazo[2,1-*b*][1,3]oxazoles  
21 (“oxazoles”) by condensing epoxides with the explosive intermediate 2,4-dinitroimidazole. In  
22 the interests of improving safety, we first sought alternative conditions using 2-bromo-4-  
23 nitroimidazole (**75**; see Scheme 1A/1B).<sup>13</sup> Satisfactory results for both 2-H and 2-methyl  
24 glycidyl ethers were obtained by neat reaction with **75** in the presence of a suitable base  
25 (DIPEA, 105-108 °C) and the resulting (uncyclised) alcohol intermediates were readily  
26 transformed into the desired oxazoles **7** and **10-12** in high yield (85-90%) upon treatment  
27 with sodium hydride (DMF, 0 °C). Minor quantities (1-3%) of 5-nitroimidazooxazoles were  
28 also generated in the first step, with two examples (**15** and **87**) being isolated for comparison.  
29 The requisite epoxides (**74**, **78**, **82**,<sup>28</sup> and **86**) were acquired via standard methods, starting  
30 with (4-OCF<sub>3</sub>) benzylations of glycidol (**73**) or 2-methylprop-2-en-1-ol (**77**), or alkylations of  
31 4-(trifluoromethoxy)phenol with epibromohydrin (**81**) or 3-chloro-2-methylprop-1-ene (**84**).

46

47 To synthesise the enantiomers of **12** and **15** (**13**, **14**, **16**, and **17**), we employed cesium  
48 fluoride promoted reactions<sup>29</sup> between 4-(trifluoromethoxy)phenol and the chiral glycidyl  
49 nosylates **89** and **93** (Scheme 1C). The ether products (**90** and **94**) were then alternatively  
50 coupled with the more accessible 2-chloro-4-nitroimidazole (**91**), where the use of toluene as  
51 cosolvent (DIPEA, 80 °C) enabled better isolated yields of the more thermally labile 5-nitro  
52  
53

1  
2  
3 compounds **16** and **17** (15-16%). In the final step, sodium hydride induced cyclisation of the  
4  
5 intermediate alcohols (**92** and **95**) was completed by warming to 20 °C, giving both oxazoles  
6  
7 **13** and **14** in high yield (86-87%) and excellent ee (100%).  
8

9  
10 Reaction of the known<sup>18,30,31</sup> chiral epoxides **96** and **97** with 4-(trifluoromethoxy)phenol or  
11  
12 4'-fluorobiphenyl-4-ol in the presence of sodium hydride (Scheme 2A) also provided a direct  
13  
14 route to the enantiomers of early VL leads **7** and **8**, as recorded for **9**.<sup>18</sup> These epoxides were  
15  
16 conveniently obtained by the reaction of 2-chloro-4-nitroimidazole (**91**) with (*R*) or (*S*)-2-  
17  
18 methylglycidyl 4-nitrobenzenesulfonate (derived from the Sharpless epoxidation of 2-  
19  
20 methylprop-2-en-1-ol, **77**),<sup>31</sup> although a multistep approach<sup>18</sup> based on the 4-nitrobenzoate  
21  
22 ester derivative of (*S*)-2-methylglycidol reportedly achieved a slightly better ee for **96** (98.8%  
23  
24 vs. 95.9%).<sup>30</sup> While isolated yields of the final products **9**, **18**, **44**, and **45** were moderate (33-  
25  
26 44%), these important entities were rapidly produced in excellent chiral purities (>98% ee),  
27  
28 and a superior kilogram scale process synthesis of **9** has recently been developed.<sup>32</sup>  
29  
30

31  
32 For more efficient generation of additional analogues of **7**, we then turned to the known<sup>33</sup>  
33  
34 racemic epoxide **98** (Scheme 2B). Heating this epoxide with various phenols and sodium  
35  
36 hydride furnished the oxazole products **19-23** directly, albeit in variable yields (12-45%),  
37  
38 depending on the conditions. Alternatively, reaction of **98** with 4-(trifluoromethoxy)aniline  
39  
40 (or its N-methyl derivative) in the presence of anhydrous cobaltous chloride<sup>34</sup> gave  
41  
42 uncyclised β-anilino alcohols (**99** and **100**), which could be transformed into the novel  
43  
44 oxazoles **24** and **25** by careful treatment with sodium hydride (1.3-1.4 equiv).  
45  
46

47  
48 Next, in order to access larger quantities of the known<sup>30</sup> alcohol **26** for the preparation of  
49  
50 heteroaryl ethers, we devised an improved plan, comprising TIPS monoprotection of known<sup>30</sup>  
51  
52 diol **102**, ring closure, and desilylation under acidic conditions (Scheme 2C). Diol **102** was  
53  
54 obtained from 2-chloro-4-nitroimidazole (**91**) in two steps (85%), via dihydroxylation of the  
55  
56 new alkene **101**, and elaborated to the oxazole **104** as planned (92% from **102**; two steps).  
57  
58  
59  
60

1  
2  
3 However, attempted removal of the TIPS group using a reported acidic method (1% HCl in  
4 95% EtOH)<sup>35</sup> required prolonged heating at 45 °C (4.5 days) and was not clean, leading to a  
5 suboptimal yield of alcohol **26** (53%). Fortunately, treatment of **104** with hydrofluoric acid in  
6 acetonitrile<sup>36</sup> gave a much better result (95% yield), and **26** was easily converted into various  
7 heteroaryl ether targets (**27**, **29-31**) via sodium hydride-catalysed S<sub>N</sub>Ar reactions on the  
8 haloheterocycles **105-108**.<sup>37</sup> The isomeric pyridine **28** was also obtained in moderate yield  
9 (25%) by reaction of 6-(trifluoromethyl)pyridin-3-ol and sodium hydride with the known<sup>30</sup>  
10 epoxide **109** (Scheme 2D). By way of comparison, epoxides **98** and **109** each afforded  
11 comparable yields (55% and 51%) for scale-up of racemic VL lead **7**.  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22

23 In the 2*H* oxazole series, the synthesis of biphenyl analogues (**32-34**) was achieved in a  
24 straightforward manner (Scheme 3A), starting from epibromohydrin (**81**), and using  
25 methodology described above (except that DMF was employed in the final step to improve  
26 solubility). We then envisaged the assembly of related phenylpyridine side chains via Suzuki  
27 couplings on bromopyridinyl ether derivatives (e.g., **119** in Scheme 3B). To this end, the  
28 known<sup>27</sup> alcohol **117** was prepared in three steps from TBS-protected glycidol (**113**), via  
29 condensation with **91**, ring closure of alcohol **115**, and acid-catalysed desilylation (Scheme  
30 3B). Unfortunately, reaction of **117** with 5-bromo-2-fluoropyridine (**118**) under the optimised  
31 conditions developed for the 2-methyl congener **144** (Scheme 4B) gave a poor yield of ether  
32 **119** (9%), and attempted Suzuki couplings on this substrate (even with weak bases) resulted  
33 only in decomposition. In an attempt to obtain at least one or two examples featuring this  
34 isomer pattern, we next considered reversing the order of these final two steps. Here, the 5-  
35 aryl-2-fluoropyridines **120** and **121** were quantitatively obtained from bromide **118** but the  
36 final alkylations involving alcohol **117** gave very poor yields (<1%) of the authentic products  
37 **35** and **36**, precluding synthesis of the less electron deficient 4-fluorophenyl analogue.

1  
2  
3 To circumvent any similar complications in the preparation of the 3-pyridyl targets (**37**, **40**  
4 and **41**), a modified strategy was adopted (Scheme 3C). Here, 6-bromopyridin-3-ol (**122**) was  
5 first protected (as the ethoxymethyl ether, **123**) and then Suzuki-coupled with arylboronic  
6 acids. Following acidic deprotection, the 6-arylpyridin-3-ols (**125**,<sup>38</sup> **129**, and **133**) were  
7 alkylated with epibromohydrin (**81**) and the resulting epoxides were then elaborated to the  
8 final products (**37**, **40** and **41**), as above, in consistently good yields (56-59% over the last 2  
9 steps). For the enantiomers of **37** (**38** and **39**), we varied this route by reacting the (NaH-  
10 generated) anion of arylpyridinol **125**<sup>38</sup> with the chiral glycidyl nosylates **89** and **93** (Scheme  
11 3D). The resulting ether products (**136** and **138**) were again coupled with 2-chloro-4-  
12 nitroimidazole (**91**), using toluene as cosolvent (DIPEA, 80 °C) in order to obtain better  
13 quantities of the 5-nitro isomers **42** and **43** (10-12% yield). Alcohols **137** and **139** were then  
14 ring closed to the oxazoles **38** and **39** in excellent yields (87-89%), as above.

Methods for the preparation of biaryl analogues and some soluble bioisosteres in the 2-  
methyl oxazole series are outlined in Scheme 4. Epoxide **141** (sourced directly<sup>39</sup> from the  
commercial chloride **140**) was converted in two steps to the 4-iodophenoxy precursor **143**,  
with Suzuki couplings then delivering the biphenyl analogues **8**, **46**, and **47** (Scheme 4A).  
The bromopyridinyl ethers **144** and **147** (obtained from alcohol **26**, and epoxide **98**,  
respectively) also proved to be effective Suzuki substrates for creating phenylpyridine and  
bipyridine derivatives (**48-56**; Scheme 4B/4C), although for bipyridines **55** and **56** it was best  
to use a weaker base (KHCO<sub>3</sub>). Furthermore, in the case of bipyridine **54**, it was necessary to  
employ a copper(I) additive,<sup>40</sup> in order to circumvent facile protodeboronation of the required  
2-pyridylpinacol boronate **145** (Scheme 4B). Arylated cyclic amine targets (**57** and **58**) were  
readily achieved by reaction of epoxide **109** with the commercial amines (**148** and **150**),  
followed by (NaH-induced) ring closure of the resulting alcohols (**149** and **151**; Scheme 4D).

1  
2  
3 Lastly, the *O*-carbamate **59** was made in high yield (86%) by chloroformylation of alcohol **26**  
4  
5 and one-pot coupling with arylpiperazine **148** (Scheme 4E).<sup>41</sup>  
6

7  
8 To conclude this SAR study, several heterocyclic ring A analogues of **7** were synthesized  
9  
10 from epoxide **86** (Scheme 5). Thus, similar condensations (DIPEA, 104-105 °C) of **86** with 2-  
11  
12 nitroimidazole (**152**), 5-bromo-3-nitro-1,2,4-triazole (**157**), or 3,5-dinitroimidazole (**158**) each  
13  
14 provided heterobicyclic products directly, although **152** gave equivalent yields of oxazole **61**  
15  
16 and its barely separable alcohol precursor **153** (Scheme 5A). Treatment of the latter with  
17  
18 sodium hydride (DMF, 0-20 °C) readily cyclised this to **61**, in agreement with a recent  
19  
20 report.<sup>42</sup> In the case of 5-bromo-3-nitro-1,2,4-triazole (**157**), a separable mixture of nitro- and  
21  
22 bromo-substituted products (**70** and **71**) was obtained in a ratio of 3:2 (Scheme 5D),  
23  
24 consistent with initial alkylation at the 1- or 2-positions of the triazole, followed by  
25  
26 intramolecular substitution of the adjacent bromine or nitro group by the intermediate  
27  
28 alcohol.<sup>43</sup> Reaction of epoxide **86** with 3,5-dinitroimidazole (**158**) yielded mainly oxazole **72**  
29  
30 (66%), together with a small amount of alcohol **159** (Scheme 5E).  
31  
32  
33

34  
35 Finally, alternative condensation of epoxide **86** with 2,4-dibromoimidazole (**154**) (DIPEA,  
36  
37 toluene, 109 °C) produced a resolvable mixture of two uncyclised alcohols (**155** and **156**, in a  
38  
39 2.4:1 ratio; Scheme 5B), which were transformed into the isomeric oxazoles **62** and **67** upon  
40  
41 mild heating of their preformed anions (NaH, DMF, 45-55 °C). Bromide **62** was converted  
42  
43 into the desired methyl sulfone **66** (regarded as a potential bioisostere of **7**) via lithiation and  
44  
45 quenching with methyl disulfide (to give thioether **65**), followed by oxidation (*m*-CPBA),  
46  
47 after an attempted copper(I) iodide/*L*-proline sodium salt-induced coupling of **62** with sodium  
48  
49 methanesulfinate<sup>44</sup> proved unsatisfactory (7% yield of crude **66**). Similar lithiation of **62** and  
50  
51 quenching with DMF also gave the aldehyde **63**, which was easily reduced (NaBH<sub>4</sub>) to  
52  
53 alcohol **64**. Methyl sulfone **66** had earlier been sought via displacement of the nitro group in  
54  
55 **7** by methanethiol, based on previous observations. Here, treatment of **7** with methanethiol  
56  
57  
58  
59  
60

1  
2  
3 and triethylamine (10 equiv in MeOH, 0-10 °C) furnished only one major product, **68**, which  
4  
5 upon oxidation gave sulfone **69** (Scheme 5C). A survey of the literature<sup>45-47</sup> had suggested  
6  
7 that *cine*- or *ipso*-substitution was possible; therefore, we studied compounds **7**, **61**, **62**, **65**,  
8  
9 **67-69**, and a 5-nitro intermediate (**114**) by 2D NMR experiments (e.g., NOESY, ROESY,  
10  
11 HSQC, and HMBC). The NOE evidence and <sup>13</sup>C NMR chemical shift data unambiguously  
12  
13 established the assigned structures (see Supporting Information), although an absence of any  
14  
15 three bond correlations between H-5 and C-3 in the HMBC experiments (when four bond  
16  
17 correlations between H-6 and C-3 were apparent) was initially misleading. Weakly observed  
18  
19 or missing long range correlations (due to the wide range of <sup>n</sup>J<sub>CH</sub> spin coupling constants, 1 to  
20  
21 50 Hz)<sup>48</sup> constitute a well-known deficiency of the standard HMBC experiment, but recent  
22  
23 HMBC variants also possess some disadvantages (e.g., reduced signal to noise).<sup>49</sup> Thus, it  
24  
25 was verified that thioether **68** was the product of *cine*-substitution,<sup>47</sup> in a fashion reminiscent  
26  
27 of the Ddn-catalysed addition of hydride to the unsubstituted imidazole carbon atoms of **4**  
28  
29 and **5**, leading to loss of the adjacent nitro group (and production of nitric oxide in *M. tb*).<sup>22,23</sup>

31  
32  
33  
34

## 35 RESULTS AND DISCUSSION

36  
37  
38 Tables 1 and 2 present *in vitro* antiparasitic and antitubercular data for 67 compounds (6  
39  
40 known) from mainly the nitroimidazooxazole class, prepared in two collaborative projects.  
41  
42 For the TB studies, compounds were screened in two *M. tb* (strain H37Rv) growth inhibition  
43  
44 assays, MABA and LORA, respectively conducted under either aerobic (replicating) or  
45  
46 hypoxic (non-replicating) conditions, as described.<sup>50,51</sup> Given that both **4** and **5** exhibit at least  
47  
48 two distinct mechanisms of action against TB, depending on the oxygenation environment,<sup>22</sup>  
49  
50 the LORA assay was regarded as a useful starting tool to identify analogues that may be more  
51  
52 efficient at killing persistent subpopulations of *M. tb in vivo*.<sup>51,52</sup> Recorded MIC values (for a  
53  
54 ≥90% growth inhibitory effect) are the mean of at least two independent determinations.  
55  
56  
57  
58

60

1  
2  
3 From 2010-2012, in collaboration with DNDi, new analogues of lead oxazoles **7** and **8**  
4 were screened against *L. don* in a macrophage-based luciferase assay<sup>25</sup> at CDRI, albeit only  
5 single determinations of the IC<sub>50</sub> values were obtained, limiting reliable SAR interpretation.  
6  
7 Therefore, a wider set of compounds was later evaluated in at least duplicate *in vitro* assays  
8  
9 against three tropical protozoan parasites (*L. inf*, *T. cruzi*, and *T. brucei*) at the University of  
10  
11 Antwerp (LMPH).<sup>53</sup> Here, the *L. inf* assay employed primary peritoneal mouse macrophages  
12  
13 as the host cell for the amastigotes, whereas the *T. cruzi* assay utilised human lung fibroblasts  
14  
15 (MRC-5 cells); compounds having mean IC<sub>50</sub> values below 1 μM were considered to be  
16  
17 highly active. Cytotoxicity on MRC-5 cells was also measured and almost all of the 67  
18  
19 compounds tested could be regarded as non-toxic (IC<sub>50</sub>s >30 μM, most >64 μM), in broad  
20  
21 agreement with assessments on VERO cells (data not shown).<sup>50</sup>  
22  
23  
24  
25  
26

27 In the design of new analogues of **7** and **8**, two strategies were employed to enhance  
28  
29 aqueous solubility while minimising the risk of major potency loss.<sup>20,21</sup> First, we focused on  
30  
31 reducing lipophilicity (probed using CLogP predictions derived from ACD LogP/LogD  
32  
33 software, version 12.0; Advanced Chemistry Development Inc., Toronto, Canada) via the  
34  
35 replacement of benzene rings by pyridine, or closely related heterocycles (*viz.* pyrimidine,  
36  
37 pyrazine, and pyridazine). This approach enabled CLogP reductions of up to 2.3 units  
38  
39 (typically ~1.1 units for a single pyridine substitution, although the predicted data displayed  
40  
41 some variation between isomers). Second, we evaluated the removal of full aromaticity from  
42  
43 the side chain by the incorporation of a saturated heterocycle (e.g., piperazine or piperidine)  
44  
45 in combination with a terminal aromatic ring. Arylated cyclic amines are known bioisosteres  
46  
47 for biaryl moieties<sup>21</sup> and can provide improved solubility via salt formation, as well as by the  
48  
49 disruption of molecular planarity and symmetry.<sup>54</sup> Kinetic aqueous solubility values at pH=7  
50  
51 were determined for selected active compounds, using dry powder forms, while analogous  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 data at pH=1 were measured for examples containing basic functionalities that could form  
4  
5 hydrochloride salts (based on calculated pK<sub>a</sub> estimates derived from similar ACD software).  
6  
7

### 8 9 *1. Initial studies relevant to preclinical candidate selection*

10  
11 The investigations began in late 2009 with the proof-of-concept *in vivo* assessment of  
12  
13 oxazoles **7** and **8** in a mouse model of VL at the London School of Hygiene and Tropical  
14  
15 Medicine (LSHTM). The selection of these two candidates was based on a combination of  
16  
17 their promising activities in an *L. don*-infected macrophage assay conducted at the Swiss  
18  
19 Tropical Institute (later confirmed at CDRI) and reasonable conjecture for their better  
20  
21 metabolic stabilities in comparison to other similarly active analogues (e.g., **11**). In the event,  
22  
23 both **7** and **8** provided outstanding efficacy in this *L. don* model at 50 mg/kg (99.9 to 100%  
24  
25 reduction of the liver parasite burden, after oral dosing once daily for 5 days) and subsequent  
26  
27 dose-response experiments (Table 3) established that **7** was the most effective lead (ED<sub>50</sub>s  
28  
29 were 3.0 and 4.8 mg/kg for **7** and **8**, respectively). This result was consistent with **7** having  
30  
31 superior mouse microsomal stability (79% vs. 57% parent remaining after 30 min, Table 3),  
32  
33 better aqueous solubility (16-fold), and a more favourable mouse pharmacokinetic profile  
34  
35 (lower clearance, greater exposure, and higher oral bioavailability; Table 4 and Supporting  
36  
37 Information, Figure S1) in comparison to **8**.  
38  
39

40  
41  
42 The more stringent chronic infection hamster model of VL is considered the gold standard  
43  
44 *in vivo* assay due to its similar pathology to human disease.<sup>55</sup> Here, 5 and 10 day assessments  
45  
46 of **7** and **8** at CDRI led to opposing conclusions on which oxazole was better (Supporting  
47  
48 Information, Table S3); therefore, the enantiomers of both compounds were prepared. In the  
49  
50 mouse model, the *R* enantiomer of **7** (**9**) was greatly superior to the *S* enantiomer (**18**) and  
51  
52 was slightly better than **7** itself (83%, 8%, and 64% inhibition at 3.13 mg/kg, respectively;  
53  
54 Table 3). This was in good agreement with the microsomal stability results (Table 3) and *L.*  
55  
56 *inf* IC<sub>50</sub> data (Table 1) showing a 4.5-fold potency difference between **9** and **18**. In contrast,  
57  
58  
59  
60

1  
2  
3 although the *R* enantiomer of **8** (**44**) was also better than the *S* enantiomer (**45**) in this model,  
4  
5 it was less active than **8** itself (36% vs. 68% at 6.25 mg/kg; Table 3), indicating reduced oral  
6  
7 exposure (**44** and **45** gave sparing aqueous solubilities of ~0.07 µg/mL). A comparative  
8  
9 appraisal of **7**, **9**, and **18** in the CDRI hamster model (Supporting Information, Table S3)  
10  
11 confirmed the preminent activity of the *R* enantiomer (**9**) over the *S* form (**18**) and **7** itself, at  
12  
13 all dose levels.<sup>25</sup> Furthermore, dose-response evaluations of **9** and the TB drug delamanid (**5**)  
14  
15 in a similar *L. inf* infected hamster model at LMPH also corroborated the excellent *in vivo*  
16  
17 efficacy of **9** (>99% inhibition in 3 target organs at 25 mg/kg; Table 5), whereas **5** displayed a  
18  
19 weak effect (22-66% at 50 mg/kg), consistent with its poor *in vitro* potency (IC<sub>50</sub> 7.1 µM). In  
20  
21 view of these findings, the decision was made to proceed with **9** as a lead candidate for VL.  
22  
23

24  
25 While the initial *in vivo* work was in progress, the oxazole analogues in hand (**7**, **8**, **10-12**,  
26  
27 **46**, and **47**) were screened against *L. don* in the macrophage-based luciferase assay at  
28  
29 CDRI.<sup>25</sup> Based on these results (Table 1) and some encouraging microsomal stability data  
30  
31 (Table 3), two additional compounds were identified as worthy of investigation in the VL  
32  
33 mouse model. These were the (6-fold) more potent des-methyl analogue of **7** (**12**: IC<sub>50</sub> 0.005  
34  
35 µM) and the 4-trifluoromethoxy analogue of **8** (**47**: IC<sub>50</sub> 0.05 µM). However,  
36  
37 counterintuitively to our previous work,<sup>19</sup> **47** was markedly inferior to **8** for VL (only 42%  
38  
39 inhibition at 25 mg/kg), while the more potent lead **12** also displayed slightly lower efficacy  
40  
41 than **7** (89% inhibition at 6.25 mg/kg; Table 3). To confirm the latter result, we examined the  
42  
43 enantiomers of **12** (**13** and **14**), but surprisingly, while the *R* form (**13**) was preferred *in vitro*  
44  
45 (Table 1), both stereoisomers had an equivalent effect *in vivo* (~75% at 6.25 mg/kg; Table 3).  
46  
47

48  
49 Examination of the pharmacokinetic properties of selected compounds afforded further  
50  
51 insight (Table 4), revealing that **12** had a higher rate of clearance than **7**, gave a lower  
52  
53 exposure level, and had a concomitantly reduced oral bioavailability (52% vs. 79%), likely  
54  
55 due in part to its 4-fold lower aqueous solubility (Table 3). Furthermore, while **47** did show  
56  
57  
58  
59  
60

1  
2  
3 better metabolic stability than **8** (decreased clearance and longer half-life; Table 4), it also  
4  
5 suffered from poor oral absorption ( $C_{\max}$  0.29  $\mu\text{g/mL}$ ; see Supporting Information, Figure  
6  
7 S1), resulting in modest oral bioavailability (18% *cf.* 63% for **8**). Again, this was consistent  
8  
9 with the 11-fold lower aqueous solubility of **47** compared to **8** (Table 3) and suggests the  
10  
11 need for stronger oral formulations when evaluating such sparingly soluble compounds.  
12  
13 Thus, the early selection of **9** for advanced development<sup>12</sup> was validated by the discovery of  
14  
15 inferior *in vivo* results for the few alternative candidates that were assessed at the time.  
16  
17

18  
19 Following the demonstration of suitable *in vivo* efficacy and *in vivo* pharmacokinetics, drug  
20  
21 discovery for leishmaniasis typically requires several additional ADME and safety studies.<sup>56</sup>  
22  
23 For example, many nitroheterocyclic compounds provide positive results in the Ames test for  
24  
25 mutagenicity; indeed, the development of an early 6-nitroimidazooxazole lead for TB (CGI-  
26  
27 17341) was halted following such a discovery.<sup>15</sup> Extensive investigation by Otsuka  
28  
29 Pharmaceutical Co. established that the introduction of heteroatoms and larger side chain  
30  
31 functionality (e.g., **5**) overcame this effect<sup>18,57</sup> and both **8** and **9**<sup>26</sup> were Ames negative. Other  
32  
33 safety factors (e.g., hERG, CYP inhibition, potential for drug-drug interactions) were also  
34  
35 broadly acceptable for **9**,<sup>26</sup> which additionally satisfied such criteria as high stability, low cost  
36  
37 of synthesis and suitability for once-per-day oral administration noted in the proposed target  
38  
39 product profile for a VL drug.<sup>58</sup> Oral treatment for VL offers many important advantages,  
40  
41 including convenience and improved patient compliance; it also enables direct delivery of the  
42  
43 absorbed drug to the liver, a major parasite population site.<sup>26</sup> Therefore, the repositioning of **9**  
44  
45 for VL may represent a significant medical breakthrough for this highly neglected disease.  
46  
47  
48

## 50 51 2. SAR of nitroimidazooxazoles for VL

52  
53 In an attempt to better understand the SAR for VL (with a view to further improving drug-  
54  
55 like features, e.g., solubility and safety), additional oxazoles were prepared and screened, first  
56  
57 at CDRI, and then at LMPH. The latter testing confirmed (Table 1) that this class had no  
58  
59  
60

1  
2  
3 obvious potential for treating HAT (*T. brucei* IC<sub>50</sub>s >1 μM, most >64 μM), nor any clear  
4  
5 utility for Chagas disease (*T. cruzi* IC<sub>50</sub>s mostly 1-3 μM, and no new leads were better than **5**  
6  
7 or **8**), so the major focus on VL was justified. Nevertheless, in light of the recently reported  
8  
9 efficacy of fexinidazole (a 5-nitroimidazole derivative) in a mouse model of VL,<sup>59</sup> one  
10  
11 fundamental question was whether 5- or 6-nitroimidazooxazoles were preferred. However, an  
12  
13 inspection of the data for **15-17** (5-nitro isomers of **12-14** above) immediately showed that  
14  
15 the 5-nitro analogues were more than two orders of magnitude less effective against *L. inf.*  
16  
17

18  
19 Having established this, compounds **19-23** initially examined the influence of the phenyl  
20  
21 ring substituent. Interestingly, while the single determination CDRI data (*L. don*) appeared to  
22  
23 indicate a clear advantage for 4-trifluoromethoxy (**7**), this was not supported by the mean  
24  
25 IC<sub>50</sub> results vs. *L. inf.*, which pinpointed only the 4-phenoxy analogue (**23**) as being  
26  
27 significantly less active, with the remaining compounds (including **7**) falling within a ca. 2-  
28  
29 fold potency range. Replacement of the side chain linking oxygen atom in **7** by nitrogen (**24**  
30  
31 and **25**) was also very well tolerated (*L. inf.* IC<sub>50</sub>s ≤1.5-fold apart), and, in the case of **24**, this  
32  
33 allowed a 6-fold solubility improvement (albeit, this compound seemed to be less stable than  
34  
35 **7**). In contrast, removal of the aryl moiety (alcohol **26**; ΔCLogP -3.4 units over **7**) led to a 55-  
36  
37 fold loss in VL activity, suggesting that an aryl-based side chain was necessary (as for TB).  
38  
39

40  
41 Therefore, we next investigated a small set of trifluoromethyl-substituted heteroaryl ethers  
42  
43 (**27-31**). This design concept was based on some partial success with employing  
44  
45 trifluoromethylpyridine as a more soluble substitute for trifluoromethoxyphenyl in our  
46  
47 previous TB studies.<sup>20,21,37</sup> Pleasingly, pyridine **27** (*L. inf.* IC<sub>50</sub> 0.24 μM) was slightly more  
48  
49 potent than both **7** and the direct phenyl equivalent **22**, and was 3-fold more soluble than **7**  
50  
51 (11 μg/mL). However, less lipophilic analogues of **27** (**28-31**) gave 2- to 6-fold poorer IC<sub>50</sub>  
52  
53 values against the parasite, despite in two cases (**28**, **30**) providing superior solubility.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 The SAR focus then switched to targets with phenylpyridine side chains, which could be  
4 regarded<sup>20</sup> as more soluble mimics of the biphenyl lead **8**. For completeness, the relatively  
5 insoluble *2H* biphenyls **32-34** were first evaluated and found to be 2- to 6-fold more active  
6 than their 2-methyl counterparts (**8**, **46**, and **47**), similar to the 2-fold higher *L. inf* potency of  
7 **12** vs. **7**. The *2H* phenyl-2-pyridines **35** and **36** had comparable or up to 6-fold reduced  
8 activities compared to the biphenyls **33** and **34**, respectively. Conversely, *2H* phenyl-3-  
9 pyridine derivatives **37**, **40** and **41** were noteworthy for the exceptional potency of the 4-  
10 fluoro compound **37** (*L. inf* IC<sub>50</sub> 0.03 μM), which was 11-fold better than **7** and 25-fold  
11 superior to the 4-trifluoromethoxy analogue **41**.  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22

23 Similar SAR trends were revealed in the 2-methyl series where, for phenyl-3-pyridine  
24 derivatives (**51-53**), the 4-fluoro compound **51** (*L. inf* IC<sub>50</sub> 0.13 μM) was overwhelmingly  
25 more active than congeners **52** and **53** (by 40- to 85-fold). By contrast, in the less soluble and  
26 more lipophilic (ΔCLogP +0.6 units) isomeric phenyl-2-pyridine series (**48-50**), the 4-fluoro  
27 compound **48** (*L. inf* IC<sub>50</sub> 2.9 μM) was no better than biphenyl lead **8** or close analogue **49**,  
28 although the 4-trifluoromethoxy derivative **50** was inferior. It was interesting to observe that  
29 neither **37** nor **51** showed enhanced potencies against the other parasites (or TB) and that both  
30 compounds displayed ~5-fold better aqueous solubility than **8** at neutral pH, in harmony with  
31 their decreased lipophilicities (ΔCLogP -1.1 to -1.5 units). This solubility differential over **8**  
32 was considerably larger at low pH (>2000-fold; Table 3), suggesting further promise.  
33 Therefore the enantiomers of **37** (**38** and **39**) were also prepared and assessed, together with  
34 their 5-nitro isomers (**42** and **43**). Here, unexpectedly, the *S* enantiomer **39** was the most  
35 active (2-fold over **38**), while the 5-nitro analogues were 3 orders of magnitude less effective.  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51

52 Overall, given the superior *in vivo* efficacy of **8** compared to **47** and the much higher *in*  
53 *vitro* potencies of **37** and **51**, it did appear that a 4-fluoro substituent in the terminal ring was  
54 preferred for VL. Therefore, in the remaining compounds (**54-59**) we retained this element  
55  
56  
57  
58  
59  
60

1  
2  
3 and probed further modifications expected to improve solubility. Commencing with the  
4  
5 bipyridines **54-56**, the most synthetically challenging isomer **54** was found to be the best (*L.*  
6  
7 *inf* IC<sub>50</sub> 0.14 μM), having >20-fold higher potencies than the related phenylpyridine **48** and  
8  
9 the biphenyl congener **8**, and 13- to 16-fold greater aqueous solubility than these compounds  
10  
11 at neutral pH (in accordance with its reduced lipophilicity, ΔCLogP -1.1 to -1.6 units).  
12  
13 Importantly, more structurally diverse phenylpiperazine and phenylpiperidine analogues (**57**  
14  
15 and **58**) also retained excellent activities (*L. inf* IC<sub>50</sub>s 0.20 and 0.23 μM). As noted above,  
16  
17 phenylpiperazine and phenylpiperidine are soluble bioisosteres for biphenyl and these  
18  
19 moieties are now appearing in many new drug candidates.<sup>60,61</sup> Here, **57** and **58** were  
20  
21 respectively 61-fold and 11-fold more soluble than **8** at neutral pH and formed nicely soluble  
22  
23 hydrochloride salts at low pH (19-23 mg/mL), in line with their calculated pKa values of 5.9  
24  
25 and 7.3. Finally, based on previous success with an arylpiperazine carbamate analogue of **4**  
26  
27 for TB,<sup>41</sup> carbamate **59** was studied, but the additional carboxy group proved detrimental for  
28  
29 VL (8.5-fold potency loss). There was also a poor tolerance for longer side chains (**60** and **5**).  
30  
31  
32  
33

34 With these SAR results in hand, the next stage of this work was to assess microsomal  
35  
36 stability and *in vivo* efficacy for the best new leads. Six racemic compounds (pyridine **27**,  
37  
38 phenylpyridines **37** and **51**, bipyridines **54** and **56**, and phenylpiperazine **57**) were selected as  
39  
40 representative of both potency and solubility optimisations for the new side chain classes  
41  
42 investigated here. Unsurprisingly, these diverse compounds demonstrated a wide range of  
43  
44 metabolic stabilities (Table 3) following 1 h exposures to human and mouse liver microsomes  
45  
46 (HLM and MLM). While all compounds showed broadly acceptable stabilities towards HLM  
47  
48 (~50% or more parent remaining), phenylpyridine **51** and phenylpiperazine **57** displayed low  
49  
50 stabilities toward MLM (14-21% parent), with the others having moderate MLM stabilities  
51  
52 (47-69% parent). The most stable compounds were pyridine **27** and bipyridine **56**, and a 2-H  
53  
54 substituent (**37**) appeared to reduce the rate of MLM metabolism (*cf.* 2-methyl derivative **51**).  
55  
56  
57  
58  
59  
60

1  
2  
3 Nevertheless, upon *in vivo* evaluation in the mouse model of VL (dosing orally at 25 mg/kg  
4 for 5 consecutive days), all candidates except the least potent one (bipyridine **56**) provided  
5 essentially total parasite clearance (>99.5%), similar to **7**, **8**, and **12**. At 6.25 mg/kg, the more  
6 rapidly metabolised phenylpiperazine **57** demonstrated poor efficacy (16% inhibition),  
7 whereas pyridine **27** (83%) was very similar to the des-methyl phenyl ether **12** (89%),  
8 bipyridine **54** was highly effective (96%), and phenylpyridines **37** and **51** both achieved a  
9 100% cure (Figure 2 and Table 3). From further dose reductions on **37**, **51**, and **54**, it was  
10 subsequently established that the highly potent *2H* phenylpyridine **37** was the most active  
11 lead (98% inhibition at 1.56 mg/kg, *cf.* <50% for **9**, **51**, and **54**), and a final head-to-head  
12 assessment of its enantiomers determined that the *S* form was marginally preferred (ED<sub>50S</sub> 1.3  
13 and 1.1 mg/kg for **38** and **39**), despite demonstrating inferior MLM stability.

25  
26

27 As discussed, a key objective of this work was to identify backups to **9** having an improved  
28 physicochemical/pharmacological profile. From our study of nitroimidazooxazoles, we have  
29 discovered several new racemic analogues (e.g., bipyridine **54**, and phenylpyridines **37** and  
30 **51**) with very high *in vivo* efficacies in a mouse model of VL, broadly comparable to **9**.  
31 However, **54** could not be regarded as a good candidate for further development due to its  
32 high synthetic difficulty, while the low metabolic stability of phenylpyridine **51** toward MLM  
33 would not bode well for its assessment in the more stringent hamster model (where faster  
34 rates of metabolism were often observed). Thus, the best new racemic lead identified here  
35 was the phenylpyridine **37**, and the most active enantiomer of **37** was **39**. With improved  
36 aqueous solubility under acidic conditions (a calculated pK<sub>a</sub> value of 3.73), acceptable  
37 metabolic stability toward HLM, and excellent *in vivo* efficacy in the mouse model of VL,  
38 this compound may warrant further investigation as a potential new antileishmanial agent.

### 55 3. SAR of new heterocyclic analogues for NTDs

56  
57  
58  
59  
60

1  
2  
3 The mechanism of action of these nitroimidazooxazoles against VL is currently unknown.  
4  
5 It has recently been disclosed that the parasite *L. don* does not possess a homologue of the *M.*  
6  
7 *tb* nitroreductase Ddn and that compounds such as **4** are not activated by the same type I  
8  
9 nitroreductase that operates on fexinidazole.<sup>62</sup> In addition to this, *L. don* reportedly does not  
10  
11 possess the mycolic acid biosynthetic pathway that is present in *M. tb* and inhibited by **4** and  
12  
13 **5** under aerobic conditions.<sup>59</sup> Therefore, as an extension to the current SAR study, we were  
14  
15 interested in ascertaining which elements of the nitroheterocyclic ring system of **7** were  
16  
17 essential for the antiparasitic activities observed (*L. inf*, *T. cruzi*) and whether or not any new  
18  
19 ring A analogues could become useful leads. The des-nitro congener of **7** (**61**) was inactive  
20  
21 against VL but unexpectedly retained similar potency to **7** against *T. cruzi* (IC<sub>50</sub> 2.1 μM;  
22  
23 Table 2); therefore, a variety of alternative imidazole ring substituents (e.g., Br, CHO,  
24  
25 CH<sub>2</sub>OH, SMe, SO<sub>2</sub>Me) were evaluated (**62-69**). As expected, such compounds showed  
26  
27 almost no utility for VL, but the 5-bromo (**67**) and 5-methylthio (**68**) analogues provided  
28  
29 enhanced antitrypanosomal potencies (*T. cruzi* IC<sub>50</sub>s 0.13 and 0.58 μM; 6-substituted  
30  
31 congeners were notably inferior). It is attractive to speculate that the inactivity of **61-69**  
32  
33 against *L. inf* may point to a specific requirement for the 6-nitro group of **7** in the mechanism  
34  
35 of action, beyond simply electronic or protein binding effects. In this work, we have shown  
36  
37 that the 6-nitro group of **7** can readily undergo *cine*-substitution by thiolate. Since it has been  
38  
39 established that nitric oxide is critical to *Leishmania*,<sup>63</sup> the known capacity of these compounds  
40  
41 to produce nitric oxide (via loss of the nitro group as nitrous acid) might still be a factor in  
42  
43 their VL activity if specific *nucleophilic* activation (e.g., by an active site cysteine thiolate or  
44  
45 hydride)<sup>23</sup> could occur via some other enzyme system within the parasite.  
46  
47  
48  
49  
50  
51

52 The remaining compounds in Table 2 (**70-72**) investigated replacement of the imidazole  
53  
54 ring by triazole or pyrazole. The direct analogues of **7** (**70** and **72**) were both completely  
55  
56 inactive against *L. inf*, suggesting that in addition to the 6-nitro group, this imidazole ring is  
57  
58  
59  
60

1  
2  
3 also essential for VL activity (mimicking the structural requirements for TB activity<sup>13,64</sup>).  
4  
5 Based on measurements in the oxazine series,<sup>13</sup> the nitro reduction potentials of **72** and **7**  
6  
7 should be very similar, but **70** and **72** could not undergo the unique ring reduction chemistry  
8  
9 and nitric oxide release exhibited by **4**. Interestingly, the nitrotriazole **70** was more active  
10  
11 than **7** against *T. cruzi* (IC<sub>50</sub>s 0.59 and 1.8 μM, respectively) whereas the bromotriazole **71**  
12  
13 and nitropyrazole **72** were less active. Thus, while the 4-nitroimidazole ring of **7** appeared to  
14  
15 be essential for retaining utility against VL, a much greater degree of structural variation was  
16  
17 tolerated for Chagas disease, suggesting a different mechanism of action. The results from  
18  
19 this investigation may therefore stimulate interest in developing new agents for Chagas  
20  
21 disease from these rather novel leads.  
22  
23  
24

#### 25 26 4. SAR of nitroimidazooxazoles for TB 27

28 While the major focus of these efforts was directed towards VL, we also examined the  
29  
30 utility of the new oxazoles against TB, using the *in vitro* assays described above (Table 1).  
31  
32 Generally, it appeared that pyridine, phenylpyridine, bipyridine, phenylpiperazine,  
33  
34 phenylpiperidine, and phenylpiperazine carbamate were all useful side chains for TB,  
35  
36 consistent with findings in the nitroimidazooxazine series and fairly scant disclosures from  
37  
38 Otsuka Pharmaceutical Co.<sup>31,57</sup> It was particularly fascinating to observe that, except for **12**,  
39  
40 **14**, and **39**, all of the most active VL leads (including **7**, **8**, and **9**, but also **27**, **37**, **51**, and **54**)  
41  
42 possessed notably high antitubercular potencies in the MABA assay (MICs <0.08 μM,  
43  
44 comparable to **5**), despite exhibiting only modest growth inhibitory effects under low oxygen  
45  
46 conditions (LORA). A closer examination of monoheterocyclic side chains revealed that the  
47  
48 2-pyridine **27** (MABA MIC 0.038 μM) was indeed optimal (as for VL), but replacement of  
49  
50 the oxygen linkage in **7** by nitrogen (**24**, **25**) reduced MABA potency by 5-fold. For the new  
51  
52 biaryl side chain derivatives, phenylpyridines such as **37**, **38**, **40**, **41**, and **48-53**, as well as  
53  
54 bipyridine **54**, uniformly displayed the highest aerobic activities (MICs ≤0.05 μM), similar or  
55  
56  
57  
58  
59  
60

1  
2  
3 slightly better than the original biphenyl analogues (**8**, **46**, and **47**). However, the elusive 2*H*  
4 phenyl-2-pyridines **35** and **36** showed dramatically lower potencies in this assay (MICs of 58  
5 and 5.3  $\mu\text{M}$ ), possibly indicating reduced stability. More soluble bioisosteres containing a  
6 cyclic amine (**57-59**) also provided slightly inferior results (MABA MICs 0.13-0.29  $\mu\text{M}$ ).  
7  
8

9  
10  
11 Because of the early promise of **7** and **8** for VL, it was considered worthwhile to evaluate  
12 the enantiomers of **7** (**9** and **18**) and the *R* enantiomer of **8** (**44**) alongside pretomanid (**4**) in a  
13 mouse model of acute TB infection, dosing orally for 3 weeks (daily for 5 days each  
14 week).<sup>19,50</sup> In this assay, both **9** and **44** (100 mg/kg) showed efficacies similar to rifampicin  
15 (15 mg/kg), respectively 9.3- and 7.6-fold superior to **4**, whereas the *S* enantiomer of **7** (**18**)  
16 was slightly less efficacious than **4** (at 100 mg/kg; Figure 3). Nevertheless, the VL lead **9** was  
17 reportedly much less active than delamanid (**5**) in a comparable *M. tb* infection model.<sup>18</sup>

26  
27

## 28 CONCLUSIONS

29  
30  
31 This study began with discovery of the extraordinary utility of several antitubercular  
32 oxazole analogues against the neglected kinetoplastid disease VL. Having first identified **9** as  
33 a preferred lead for preclinical development, we later investigated its SAR, with the objective  
34 of improving aqueous solubility and other drug-like features without compromising *in vivo*  
35 efficacy. All modifications to the nitroheterocycle (*viz.* removal of the nitro group or  
36 switching its position, and replacement of the imidazole ring by pyrazole or triazole) resulted  
37 in a total loss of activity against VL (but not Chagas disease), whereas many aryl-,  
38 heteroaryl-, and heterobiaryl-based side chains were well tolerated *in vitro*. Surprisingly,  
39 there were several significant similarities in these respects to the SAR for TB, while the  
40 discovery of facile *cine*-substitution of the nitro group of **7** by thiolate was intriguing.  
41

44  
45  
46  
47  
48  
49  
50  
51  
52

53  
54 Overall, the most effective strategies to enhance aqueous solubility while maintaining or  
55 increasing potency were the replacement of phenyl rings by pyridine and the use of  
56  
57  
58  
59  
60

1  
2  
3 arylpiperazine and arylpiperidine as bioisosteres for a biaryl moiety. These strategies enabled  
4  
5 solubility improvements over **7** of 3- to 14-fold at pH = 7 and up to 6400-fold at pH = 1.  
6  
7 Assessments of stability toward HLM gave broadly acceptable results, although two  
8  
9 compounds (phenylpyridine **51** and phenylpiperazine **57**) had high MLM metabolism rates.  
10  
11 Further appraisal of six candidates in the acute infection mouse model of VL revealed three  
12  
13 racemic compounds (phenylpyridines **37** and **51**, and bipyridine **54**) that displayed efficacies  
14  
15 at least as strong as **7**. Of these, one compound (**37**) was notably superior, in line with its  
16  
17 excellent *in vitro* profile, and subsequent synthesis and evaluation of its enantiomers has  
18  
19 pinpointed the *S* form **39** as being the slightly preferred VL lead for further investigation.  
20  
21 Findings from this work may also inspire interest in these promising compounds for other  
22  
23 NTDs.  
24

## 27 28 **EXPERIMENTAL SECTION**

29  
30  
31 Combustion analyses were performed by the Campbell Microanalytical Laboratory,  
32  
33 University of Otago, Dunedin, New Zealand. Melting points were determined using an  
34  
35 Electrothermal IA9100 melting point apparatus, and are as read. NMR spectra were measured  
36  
37 on a Bruker Avance 400 spectrometer at 400 MHz for <sup>1</sup>H and 100 MHz for <sup>13</sup>C and are  
38  
39 referenced to Me<sub>4</sub>Si or solvent resonances. Chemical shifts and coupling constants are recorded  
40  
41 in units of ppm and hertz, respectively. High-resolution chemical ionisation (HRCIMS) and fast  
42  
43 atom bombardment (HRFABMS) mass spectra were determined on a VG-70SE mass  
44  
45 spectrometer at nominal 5000 resolution. High-resolution electrospray ionisation (HRESIMS)  
46  
47 mass spectra were determined on a Bruker micrOTOF-Q II mass spectrometer. Low-  
48  
49 resolution atmospheric pressure chemical ionisation (APCI) mass spectra were obtained for  
50  
51 organic solutions using a ThermoFinnigan Surveyor MSQ mass spectrometer, connected to a  
52  
53 Gilson autosampler. Optical rotations were measured on a Schmidt + Haensch Polartronic  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 NH8 polarimeter. Column chromatography was performed on silica gel (Merck 230-400 mesh).  
4  
5 Thin-layer chromatography was carried out on aluminium-backed silica gel plates (Merck 60  
6  
7 F<sub>254</sub>), with visualization of components by UV light (254 nm), I<sub>2</sub>, or KMnO<sub>4</sub> staining. Tested  
8  
9 compounds (including batches screened *in vivo*) were  $\geq 95\%$  pure, as determined by  
10  
11 combustion analysis (results within 0.4% of theoretical values) and/or by HPLC conducted  
12  
13 on an Agilent 1100 system, using a 150 mm x 3.2 mm Altima 5  $\mu\text{m}$  reversed phase C18  
14  
15 column with diode array detection. Finally, chiral purity was assessed by HPLC carried out  
16  
17 on a Gilson Unipoint system (322-H pump, 156 UV/vis detector), employing a 250 mm x 4.6  
18  
19 mm CHIRALCEL OD 10  $\mu\text{m}$  analytical column, or 250 mm x 4.6 mm CHIRALPAK IA or  
20  
21 CHIRALPAK AD-H 5.0  $\mu\text{m}$  analytical columns.  
22

24  
25

26 **Compounds of Table 1.** The following section details the syntheses of compounds **10-13**,  
27  
28 **15, 16, 18, 23, 24, 35, 37, 48, 55, and 57** of Table 1, via representative procedures and key  
29  
30 intermediates, as described in Schemes 1-4. For the syntheses of all of the other compounds  
31  
32 in Table 1, please refer to Supporting Information.  
33  
34  
35

36 **Synthesis of 10 (Scheme 1A):**

37  
38 **Procedure A: 2-([4-(Trifluoromethoxy)benzyl]oxy)methyl)oxirane (74).** A solution of  
39  
40 glycidol (**73**) (303 mg, 4.09 mmol) and 4-(trifluoromethoxy)benzyl bromide (0.81 mL, 5.06  
41  
42 mmol) in anhydrous DMF (6 mL) under N<sub>2</sub> at 0 °C was treated with 60% NaH (246 mg, 6.15  
43  
44 mmol), then quickly degassed and resealed under N<sub>2</sub>. The resulting mixture was stirred at 20  
45  
46 °C for 7 h and then cooled (CO<sub>2</sub>/acetone), quenched with ice/aqueous NaHCO<sub>3</sub> (100 mL),  
47  
48 and extracted with EtOAc (4 x 100 mL). The extracts were washed with brine (100 mL) and  
49  
50 then evaporated to dryness under reduced pressure (at 30 °C), and the residue was  
51  
52 chromatographed on silica gel. Elution with 0-5% Et<sub>2</sub>O/petroleum ether first gave foreruns,  
53  
54 and then further elution with 5-10% Et<sub>2</sub>O/petroleum ether gave **74** (625 mg, 62%) as a  
55  
56  
57  
58  
59  
60

2  
3 colourless oil;  $^1\text{H NMR}$  ( $\text{CDCl}_3$ )  $\delta$  7.38 (br d,  $J = 8.7$  Hz, 2 H), 7.20 (br d,  $J = 8.7$  Hz, 2 H),  
4  
5 4.62 (d,  $J = 12.0$  Hz, 1 H), 4.56 (d,  $J = 12.0$  Hz, 1 H), 3.82 (dd,  $J = 11.5, 2.8$  Hz, 1 H), 3.43  
6  
7 (dd,  $J = 11.5, 6.0$  Hz, 1 H), 3.24-3.18 (m, 1 H), 2.82 (dd,  $J = 4.9, 4.2$  Hz, 1 H), 2.63 (dd,  $J =$   
8  
9 5.0, 2.7 Hz, 1 H); HRESIMS calcd for  $\text{C}_{11}\text{H}_{11}\text{F}_3\text{NaO}_3$   $m/z$   $[\text{M} + \text{Na}]^+$  271.0552, found  
10  
11 271.0557.  
12

13  
14 **Procedure B: 1-(2-Bromo-4-nitro-1H-imidazol-1-yl)-3-[[4-**  
15 **(trifluoromethoxy)benzyl]oxy}propan-2-ol (76).** A mixture of epoxide **74** (500 mg, 2.01  
16  
17 mmol), 2-bromo-4-nitro-1H-imidazole (**75**) (390 mg, 2.03 mmol), and DIPEA (1.75 mL, 10.0  
18  
19 mmol) in a sealed vial was stirred at 107 °C for 13 h. The resulting cooled mixture was  
20  
21 dissolved in  $\text{CH}_2\text{Cl}_2$  and added to ice/aqueous  $\text{NaHCO}_3$  (50 mL), then extracted with  $\text{CH}_2\text{Cl}_2$   
22  
23 (5 x 50 mL). The extracts were evaporated to dryness under reduced pressure and the residue  
24  
25 was chromatographed on silica gel. Elution with 0-1% EtOAc/ $\text{CH}_2\text{Cl}_2$  first gave foreruns, and  
26  
27 then further elution with 1-2% EtOAc/ $\text{CH}_2\text{Cl}_2$  gave **76** (538 mg, 61%) as a cream solid: mp  
28  
29 ( $\text{CH}_2\text{Cl}_2$ /pentane) 80-81 °C;  $^1\text{H NMR}$  ( $\text{CDCl}_3$ )  $\delta$  7.95 (s, 1 H), 7.35 (br d,  $J = 8.7$  Hz, 2 H),  
30  
31 7.23 (br d,  $J = 7.9$  Hz, 2 H), 4.57 (s, 2 H), 4.20 (dd,  $J = 13.6, 2.9$  Hz, 1 H), 4.18-4.10 (m, 1  
32  
33 H), 4.07 (dd,  $J = 13.4, 7.1$  Hz, 1 H), 3.59 (dd,  $J = 9.6, 4.2$  Hz, 1 H), 3.46 (dd,  $J = 9.6, 5.3$  Hz,  
34  
35 1 H), 2.61 (d,  $J = 5.0$  Hz, 1 H); HRESIMS calcd for  $\text{C}_{14}\text{H}_{14}\text{BrF}_3\text{N}_3\text{O}_5$   $m/z$   $[\text{M} + \text{H}]^+$  442.0044,  
36  
37 440.0063, found 442.0044, 440.0061.

3 chromatographed on silica gel. Elution with CH<sub>2</sub>Cl<sub>2</sub> first gave foreruns, and then further  
4  
5 elution with 0-2% EtOAc/CH<sub>2</sub>Cl<sub>2</sub> gave **10** (383 mg, 90%) as a cream solid: mp  
6  
7 (CH<sub>2</sub>Cl<sub>2</sub>/hexane) 134-135 °C; <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 7.53 (s, 1 H), 7.29 (br d, *J* = 8.7 Hz, 2 H),  
8  
9 7.20 (br d, *J* = 8.0 Hz, 2 H), 5.46-5.38 (m, 1 H), 4.60 (s, 2 H), 4.32 (dd, *J* = 10.0, 8.6 Hz, 1  
10  
11 H), 4.26 (dd, *J* = 10.0, 6.5 Hz, 1 H), 3.89 (dd, *J* = 11.3, 3.9 Hz, 1 H), 3.78 (dd, *J* = 11.3, 3.5  
12  
13 Hz, 1 H). Anal. (C<sub>14</sub>H<sub>12</sub>F<sub>3</sub>N<sub>3</sub>O<sub>5</sub>) C, H, N.

14  
15  
16  
17 **Synthesis of 11 (Scheme 1A):**

18  
19 **1-[[2-Methylprop-2-en-1-yl]oxy]methyl]-4-(trifluoromethoxy)benzene (78).** A solution  
20  
21 of 2-methylprop-2-en-1-ol (**77**) (2.34 mL, 27.8 mmol) in anhydrous DMF (10 mL, then 2 x 2  
22  
23 mL to rinse) was added dropwise to a stirred suspension of 60% NaH (1.32 g, 33.0 mmol) in  
24  
25 anhydrous DMF (10 mL) under N<sub>2</sub> at 0 °C. After 30 min, 4-(trifluoromethoxy)benzyl  
26  
27 bromide (5.1 mL, 31.9 mmol) was added, and the mixture was stirred at 20 °C for 21 h. The  
28  
29 resulting mixture was added to ice/aqueous NaHCO<sub>3</sub> (200 mL) and extracted with 25%  
30  
31 EtOAc/petroleum ether (2 x 200 mL) and 50% EtOAc/petroleum ether (3 x 200 mL). The  
32  
33 extracts were washed with water (200 mL) and then concentrated under reduced pressure, and  
34  
35 the remaining oil was chromatographed on silica gel. Elution with petroleum ether first gave  
36  
37 foreruns, and then further elution with 0-5% CH<sub>2</sub>Cl<sub>2</sub>/petroleum ether gave **78** (6.57 g, 96%)  
38  
39 as a colourless oil, which was used directly in the next step; <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 7.37 (br d, *J*  
40  
41 = 8.7 Hz, 2 H), 7.19 (br d, *J* = 8.0 Hz, 2 H), 5.00 (m, 1 H), 4.94 (m, 1 H), 4.48 (s, 2 H), 3.94  
42  
43 (br s, 2 H), 1.77 (s, 3 H).

44  
45  
46  
47  
48 **Procedure D: 2-Methyl-2-([[4-(trifluoromethoxy)benzyl]oxy]methyl)oxirane (79).** 3-  
49  
50 Chloroperoxybenzoic acid (19.5 g of 50%, 56.5 mmol) was added to a mixture of alkene **78**  
51  
52 (6.57 g, 26.7 mmol) and disodium hydrogen phosphate (9.87 g, 69.5 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (250  
53  
54 mL) at 0 °C. The mixture was stirred at 20 °C for 3 h and then added to an ice-cold aqueous  
55  
56 solution of sodium sulphite (400 mL of 10%) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 x 400 mL). The  
57  
58  
59  
60

1  
2  
3 extracts were sequentially washed with ice-cold aqueous sodium sulphite solution (400 mL of  
4 10%), aqueous NaHCO<sub>3</sub> (400 mL), and brine (300 mL), and then the aqueous solutions were  
5 back-extracted with CH<sub>2</sub>Cl<sub>2</sub> (200 mL). The combined extracts were concentrated under  
6 reduced pressure and the remaining oil was chromatographed on silica gel. Elution with 0-  
7 15% CH<sub>2</sub>Cl<sub>2</sub>/petroleum ether first gave foreruns, and then further elution with 15%  
8 CH<sub>2</sub>Cl<sub>2</sub>/petroleum ether and CH<sub>2</sub>Cl<sub>2</sub> gave **79** (6.53 g, 93%) as a colourless oil; <sup>1</sup>H NMR  
9 (CDCl<sub>3</sub>) δ 7.37 (br d, *J* = 8.7 Hz, 2 H), 7.19 (br d, *J* = 7.9 Hz, 2 H), 4.59 (d, *J* = 12.1 Hz, 1  
10 H), 4.54 (d, *J* = 12.1 Hz, 1 H), 3.61 (d, *J* = 11.1 Hz, 1 H), 3.44 (d, *J* = 11.1 Hz, 1 H), 2.75 (d,  
11 *J* = 4.9 Hz, 1 H), 2.64 (d, *J* = 4.9 Hz, 1 H), 1.40 (s, 3 H); HRCIMS (NH<sub>3</sub>) calcd for  
12 C<sub>12</sub>H<sub>17</sub>F<sub>3</sub>NO<sub>3</sub> *m/z* [M + NH<sub>3</sub> + H]<sup>+</sup> 280.1161, found 280.1144.

13  
14 **1-(2-Bromo-4-nitro-1*H*-imidazol-1-yl)-2-methyl-3-[[4-(trifluoromethoxy)benzyl]oxy]-**  
15 **propan-2-ol (80)**. Reaction of epoxide **79** with 2-bromo-4-nitro-1*H*-imidazole (**75**) (1.1  
16 equiv) and DIPEA (7.6 equiv), using procedure B at 108 °C for 15 h, followed by  
17 chromatography of the product on silica gel, eluting with CH<sub>2</sub>Cl<sub>2</sub>, gave **80** (94%) as a pale  
18 yellow oil; <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 8.00 (s, 1 H), 7.33 (br d, *J* = 8.6 Hz, 2 H), 7.22 (br d, *J* = 8.0  
19 Hz, 2 H), 4.56 (s, 2 H), 4.15 (d, *J* = 14.8 Hz, 1 H), 4.04 (d, *J* = 14.5 Hz, 1 H), 3.39 (s, 2 H),  
20 2.51 (s, 1 H), 1.22 (s, 3 H); HRESIMS calcd for C<sub>15</sub>H<sub>16</sub>BrF<sub>3</sub>N<sub>3</sub>O<sub>5</sub> *m/z* [M + H]<sup>+</sup> 456.0200,  
21 454.0220, found 456.0197, 454.0221.

22  
23 **2-Methyl-6-nitro-2-([[4-(trifluoromethoxy)benzyl]oxy)methyl]-2,3-**  
24 **dihydroimidazo[2,1-*b*][1,3]oxazole (11)**. Reaction of alcohol **80** with NaH (1.4 equiv), using  
25 procedure C for 85 min, followed by chromatography of the product on silica gel, eluting  
26 with CH<sub>2</sub>Cl<sub>2</sub> (foreruns) and then with 0-1% EtOAc/CH<sub>2</sub>Cl<sub>2</sub>, gave **11** (87%) as a pale yellow  
27 solid: mp (CH<sub>2</sub>Cl<sub>2</sub>/hexane) 110-111 °C; <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 7.50 (s, 1 H), 7.26 (br d, *J* = 8.4  
28 Hz, 2 H), 7.19 (br d, *J* = 8.3 Hz, 2 H), 4.59 (d, *J* = 12.3 Hz, 1 H), 4.56 (d, *J* = 12.3 Hz, 1 H),

**Compounds of Table 2.** The following section details the syntheses of compounds **62** and **65** of Table 2, as described in Scheme 5. For the syntheses of all of the other compounds in Table 2, please refer to Supporting Information.

*Syntheses of 62 and 65 (Scheme 5B):*

**1-(2,4-Dibromo-1H-imidazol-1-yl)-2-methyl-3-[4-(trifluoromethoxy)phenoxy]propan-2-ol (155)** and **1-(2,5-dibromo-1H-imidazol-1-yl)-2-methyl-3-[4-(trifluoromethoxy)phenoxy]propan-2-ol (156)**. Reaction of epoxide **86** (see Supporting Information) with 2,4-dibromo-1H-imidazole (**154**) (1.05 equiv) and DIPEA in anhydrous toluene, using procedure G at 109 °C for 12 h, followed by chromatography of the product on silica gel, eluting with  $\text{CH}_2\text{Cl}_2$  (foreruns) and then with additional  $\text{CH}_2\text{Cl}_2$ , first gave the crude major product (**155**). This was further purified by chromatography on silica gel, eluting with  $\text{CH}_2\text{Cl}_2$  (to remove a minor higher running impurity) and then with 0-1%  $\text{Et}_2\text{O}/\text{CH}_2\text{Cl}_2$  (to give the product), and by additional chromatography on silica gel, eluting with 0-25%  $\text{Et}_2\text{O}/\text{petroleum ether}$  (foreruns, including excess **154**) and then with  $\text{CH}_2\text{Cl}_2$ , to give **155** (69%) as a colourless oil;  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  7.18 (s, 1 H), 7.17 (br d,  $J = 8.9$  Hz, 2 H), 6.88 (br d,  $J = 9.2$  Hz, 2 H), 4.16 (d,  $J = 14.6$  Hz, 1 H), 4.08 (d,  $J = 14.6$  Hz, 1 H), 3.86 (d,  $J = 9.0$  Hz, 1 H), 3.81 (d,  $J =$

9.1 Hz, 1 H), 2.38 (s, 1 H), 1.34 (s, 3 H); HRESIMS calcd for  $C_{14}H_{14}Br_2F_3N_2O_3$   $m/z$   $[M + H]^+$  476.9280, 474.9298, 472.9318, found 476.9276, 474.9302, 472.9326.

Further elution of the original column above with 3-5%  $Et_2O/CH_2Cl_2$  gave the crude minor product (**156**), which was further purified by chromatography on silica gel, eluting with 0-30%  $Et_2O$ /petroleum ether (foreruns, including excess **154**) and then with 0-3%  $Et_2O/CH_2Cl_2$ , to give **156** (29%) as a cream solid: mp ( $CH_2Cl_2$ /pentane) 129-131 °C;  $^1H$  NMR ( $CDCl_3$ )  $\delta$  7.17 (br d,  $J = 9.1$  Hz, 2 H), 7.05 (s, 1 H), 6.90 (br d,  $J = 9.2$  Hz, 2 H), 4.33 (d,  $J = 15.0$  Hz, 1 H), 4.19 (d,  $J = 15.1$  Hz, 1 H), 3.94 (d,  $J = 9.0$  Hz, 1 H), 3.91 (d,  $J = 9.0$  Hz, 1 H), 2.51 (s, 1 H), 1.38 (s, 3 H); HRESIMS calcd for  $C_{14}H_{14}Br_2F_3N_2O_3$   $m/z$   $[M + H]^+$  476.9280, 474.9298, 472.9318, found 476.9279, 474.9303, 472.9313.

**6-Bromo-2-methyl-2-[[4-(trifluoromethoxy)phenoxy]methyl]-2,3-dihydroimidazo[2,1-*b*][1,3]oxazole (62)**. Reaction of alcohol **155** with NaH (1.25 equiv), using procedure C at 20 °C for 20 min and then at 55 °C for 4 h, followed by chromatography of the product on silica gel, eluting with 33-50%  $CH_2Cl_2$ /petroleum ether (foreruns) and then with 50-75%  $CH_2Cl_2$ /petroleum ether, gave **62** (87%) as a cream solid (following trituration in cold pentane): mp 55-57 °C;  $^1H$  NMR ( $CDCl_3$ )  $\delta$  7.14 (br d,  $J = 9.1$  Hz, 2 H), 6.87 (br d,  $J = 9.2$  Hz, 2 H), 6.60 (s, 1 H), 4.30 (d,  $J = 9.5$  Hz, 1 H), 4.16 (d,  $J = 9.8$  Hz, 1 H), 4.04 (d,  $J = 9.8$  Hz, 1 H), 3.90 (d,  $J = 9.5$  Hz, 1 H), 1.73 (s, 3 H);  $^{13}C$  NMR ( $CDCl_3$ )  $\delta$  157.3 (C-7a), 156.6 (C-1'), 143.8 (C-4'), 122.8 (2 C, C-3',5'), 120.7 (q,  $J_{C-F} = 256.5$  Hz, 4'-OCF<sub>3</sub>), 115.8 (2 C, C-2',6'), 114.0 (C-6), 110.1 (C-5), 92.1 (C-2), 72.0 (2-CH<sub>2</sub>O), 52.1 (C-3), 23.5 (2-CH<sub>3</sub>). Anal. ( $C_{14}H_{12}BrF_3N_2O_3$ ) C, H, N.

**2-Methyl-6-(methylsulfonyl)-2-[[4-(trifluoromethoxy)phenoxy]methyl]-2,3-dihydroimidazo[2,1-*b*][1,3]oxazole (65)**. *n*-Butyllithium (0.58 mL of a 2.0 M solution in cyclohexane, 1.16 mmol) was added dropwise to a stirred solution of bromide **62** (303 mg, 0.771 mmol) in anhydrous freshly distilled THF (7 mL) under  $N_2$  at -78 °C. After 80 min

1  
2  
3 at -78 °C, methyl disulfide (0.28 mL, 3.16 mmol) was added dropwise, and the mixture was  
4  
5 stirred at -78 °C for 3.5 h, slowly warmed to -20 °C (over 1 h), stored at -20 °C for 10 h, and  
6  
7 finally stirred at 0 °C for 3 h. The reaction was then quenched with ice/aqueous citric acid (20  
8  
9 mL), and the resulting mixture was added to water (30 mL), and extracted with CH<sub>2</sub>Cl<sub>2</sub> (6 x  
10  
11 50 mL). The combined extracts were evaporated to dryness under reduced pressure and the  
12  
13 residue was chromatographed on silica gel. Elution with 0-1% Et<sub>2</sub>O/CH<sub>2</sub>Cl<sub>2</sub> first gave  
14  
15 foreruns, and then further elution with 5% Et<sub>2</sub>O/CH<sub>2</sub>Cl<sub>2</sub> gave the crude product (0.12 g) as an  
16  
17 8:1 mixture of isomers, which was crystallised from CH<sub>2</sub>Cl<sub>2</sub>/pentane, to give pure **65** (93 mg,  
18  
19 33%) as a cream solid: mp 104-106 °C; <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 7.15 (br d, *J* = 9.1 Hz, 2 H), 6.87  
20  
21 (br d, *J* = 9.2 Hz, 2 H), 6.61 (s, 1 H), 4.26 (d, *J* = 9.5 Hz, 1 H), 4.15 (d, *J* = 9.6 Hz, 1 H),  
22  
23 4.04 (d, *J* = 9.7 Hz, 1 H), 3.86 (d, *J* = 9.6 Hz, 1 H), 2.41 (s, 3 H), 1.73 (s, 3 H); <sup>13</sup>C NMR  
24  
25 (CDCl<sub>3</sub>) δ 158.7 (C-7a), 156.7 (C-1'), 143.7 (q, *J*<sub>C-F</sub> = 2.1 Hz, C-4'), 135.7 (C-6), 122.8 (2 C,  
26  
27 C-3',5'), 120.7 (q, *J*<sub>C-F</sub> = 256.4 Hz, 4'-OCF<sub>3</sub>), 115.8 (2 C, C-2',6'), 111.9 (C-5), 91.6 (C-2),  
28  
29 72.1 (2-CH<sub>2</sub>O), 51.8 (C-3), 23.5 (2-CH<sub>3</sub>), 18.7 (SCH<sub>3</sub>). Anal. (C<sub>15</sub>H<sub>15</sub>F<sub>3</sub>N<sub>2</sub>O<sub>3</sub>S) C, H, N.

30  
31  
32  
33  
34  
35 **Minimum Inhibitory Concentration Assays (MABA and LORA).** These were carried  
36  
37 out according to the published protocols.<sup>50,51</sup>

60  
**In Vitro Parasite Growth Inhibition Assays.** The activity of test compounds against the  
amastigote stage of the *L. don* parasite was assessed at CDRI using a mouse macrophage-  
based luciferase assay, carried out according to the reported procedures.<sup>25</sup> Additional assays  
measuring the growth inhibitory action of compounds against *L. inf*, *T. cruzi*, and *T. brucei*,  
and determining any cytotoxic effects on human lung fibroblasts (MRC-5 cells), were  
conducted at the University of Antwerp (LMPH), as described in a recent report.<sup>53</sup>

**Solubility Determinations.** The solid compound sample was mixed with water or 0.1 M  
HCl (enough to make a 2 mM solution) in an Eppendorf tube, and the suspension was  
sonicated for 15 min and then centrifuged at 13000 rpm for 6 min. An aliquot of the clear

1  
2  
3 supernatant was diluted 2-fold with water (or 0.1 M HCl), and then HPLC was conducted.  
4  
5 The solubility was calculated by comparing the peak area obtained with that from a standard  
6  
7 solution of the compound in DMSO (after allowing for varying dilution factors and injection  
8  
9 volumes).  
10

11 **Microsomal Stability Assays.** Studies on compounds **7-9**, **12**, **18**, and **47** (Table 3) were  
12  
13 performed by Advinus Therapeutics Ltd., 21 & 22 Phase II, Peenya Industrial Area,  
14  
15 Bangalore 560058, India, using a published protocol<sup>26</sup> in which the compound concentration  
16  
17 was 0.5  $\mu$ M and the incubation time was 30 min. Additional analyses on compounds **5**, **9**, **27**,  
18  
19 **37-39**, **51**, **54**, **56**, and **57** (Table 3) were carried out by WuXi AppTec (Shanghai) Co., Ltd,  
20  
21 288 FuTe ZhongLu, WaiGaoQiao Free Trade Zone, Shanghai 200131, China. Here, test  
22  
23 compounds (at 1  $\mu$ M) were incubated at 37 °C with liver microsomes from human, CD-1  
24  
25 mouse or hamster species in the presence of a NADPH regenerating system and phosphate  
26  
27 buffer (100 mM, pH 7.4) at 0.5 mg/mL microsomal protein (the positive controls were  
28  
29 testosterone, propafenone and diclofenac). Samples were removed at time intervals of 0, 5,  
30  
31 10, 20, 30, and 60 mins and immediately mixed with cold CH<sub>3</sub>CN (containing 0.1  $\mu$ g/mL of  
32  
33 tolbutamide as an internal standard), then centrifuged prior to analysis by LCMS/MS.  
34  
35  
36  
37

38 **In Vivo Experiments.** All animal experiments were performed according to institutional  
39  
40 ethical guidelines for animal care. Antitubercular efficacy studies in mice were approved by  
41  
42 the UIC IACUC (UIC AWA no. A3460-01; ACC application no. 12-183). For VL, mouse  
43  
44 model studies (LSHTM) were conducted under license from the UK Home Office (license  
45  
46 no. PIL 70/6997), hamster studies at CDRI were approved by the CSIR-CDRI animal ethics  
47  
48 committee (license no. 19/2009/PARA/IAEC), and hamster studies at LMPH were approved  
49  
50 by the ethical committee of the University of Antwerp (UA-ECD 2010-17).  
51  
52  
53

54 **Acute TB Infection Assay.** Each compound (including **4**, which was used as an internal  
55  
56 reference standard) was administered orally to a group of 7 *M. tb*-infected BALB/c mice at  
57  
58  
59  
60

1  
2  
3 100 mg/kg daily for 5 days a week for 3 weeks, beginning on day 11 postinfection, in  
4  
5 accordance with published protocols.<sup>19,50</sup> The results are recorded as the ratio of the average  
6  
7 reduction in colony forming units (CFUs) in the compound-treated mice /the average CFU  
8  
9 reduction in the mice treated with **4**. In this assay, **4** caused 2.5-3 log reductions in CFUs.

10  
11 **Acute VL Infection Assay (Mouse Model, LSHTM).** Test compounds were orally dosed  
12  
13 once per day for 5 consecutive days to groups of 5 female BALB/c mice infected with  $2 \times 10^7$   
14  
15 *L. donovani* amastigotes, with treatment commencing one week postinfection, as reported.<sup>25</sup>  
16  
17 Miltefosine (**3**) and AmBisome were positive controls and parasite burdens were determined  
18  
19 from impression smears of liver sections. Efficacy was expressed as the mean percentage  
20  
21 reduction in parasite load for treated mice in comparison to untreated (vehicle-only) controls.  
22  
23

24  
25 **Chronic VL Infection Assay 1 (Hamster Model, CDRI).** Golden hamsters (weighing 40-  
26  
27 45 g) were infected intracardially with  $1 \times 10^7$  *L. donovani* amastigotes and then, 15 days  
28  
29 later, all animals were subjected to splenic biopsy to assess the level of infection. Groups of  
30  
31 hamsters having an appropriate infection grading (5-15 amastigotes/100 spleen cell nuclei)  
32  
33 were treated with test compounds, starting on day 17 and dosing orally once per day for  
34  
35 either 5 or 10 consecutive days, according to the published procedure.<sup>25</sup> Post-treatment  
36  
37 splenic biopsies performed 12 days after the first dose were employed to determine the  
38  
39 intensity of infection, as previously described.<sup>25</sup>  
40  
41

42  
43 **Chronic VL Infection Assay 2 (Hamster Model, LMPH).** Golden hamsters (weighing  
44  
45 75-80 g) were infected with  $2 \times 10^7$  *L. infantum* amastigotes and, 21 days post-infection,  
46  
47 treatment groups of 6 animals each were dosed orally once per day with test compounds  
48  
49 (formulated in PEG<sub>400</sub>) for 5 consecutive days. Parasite burdens in three target organs (liver,  
50  
51 spleen, and bone-marrow) were determined by microscopic evaluation of impression smears  
52  
53 (stained with Giemsa) and efficacy was expressed as the mean percentage load reduction for  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 treated hamsters in comparison to untreated (vehicle-only) controls. Miltefosine (**3**) was  
4  
5 included as a reference drug in all experiments.  
6

7 **Mouse Pharmacokinetics.** The study was conducted by Advinus Therapeutics Ltd., 21 &  
8  
9 22 Phase II, Peenya Industrial Area, Bangalore 560058, India, according to a published  
10  
11 protocol.<sup>26</sup> Briefly, compounds were administered to groups of male Swiss Albino mice (30-  
12  
13 40 g); intravenous dosing (at 1 mg/kg) employed a solution vehicle comprising 20% NMP  
14  
15 and 40% PEG-400 in 100mM citrate buffer pH 3, while oral dosing (at 12.5 or 25 mg/kg)  
16  
17 was as a suspension in 0.08% Tween 80/0.5% carboxymethylcellulose in water. Samples  
18  
19 derived from blood plasma (at 0.083 for iv only, 0.25, 0.5, 1, 2, 4, 6, 8, 10, 24 and 48 h) were  
20  
21 centrifuged prior to analysis by LC-MS/MS and the pharmacokinetic parameters were  
22  
23 determined using WinNonlin software (Version 5.2).  
24
