

# Convenient direct syntheses of novel fused-ring CB<sub>4</sub>N<sub>5</sub> systems by nitrile hydroboration†

Robert Coult,<sup>a</sup> Mark A. Fox,<sup>a</sup> Brian Rand,<sup>b</sup> Kenneth Wade<sup>\*,a</sup> and Aidan V. K. Westwood<sup>b</sup>

<sup>a</sup> Chemistry Department, Durham University Science Laboratories, South Road, Durham, UK DH1 3LE

<sup>b</sup> School of Materials, University of Leeds, Leeds, UK LS2 9JT

Reactions between B<sub>2</sub>H<sub>6</sub> or BH<sub>3</sub>·thf (thf = tetrahydrofuran) and nitriles RC≡N (R = Me, Et, Bu<sup>t</sup> or CH<sub>2</sub>F), previously known to generate borazines (RCH<sub>2</sub>NBH)<sub>3</sub> have been found to generate also 25–37% yields of novel carboraza bicyclic systems related to dihydronaphthalene, H<sub>3</sub>B<sub>4</sub>N<sub>5</sub>(RCH<sub>2</sub>)<sub>4</sub>CHR, thus affording for the first time a direct route from commercially available acyclic reagents into mixed carbon–boron–nitrogen heterocyclic chemistry.

Bubbling diborane in nitrogen through refluxing acetonitrile was shown in 1968<sup>1</sup> to give the borazine (EtNBH)<sub>3</sub> **1** in 35–40% yield, together with what appeared (from mass spectroscopic studies) to be a complex mixture of derivatives of higher boron–nitrogen heterocyclic systems including B<sub>5</sub>N<sub>5</sub> naphthalene analogue **5** and B<sub>6</sub>N<sub>6</sub> biphenyl analogue **6**.

Re-examination of such reactions, using a wider range of nitriles and reaction conditions, has confirmed that borazines (RCH<sub>2</sub>NBH)<sub>3</sub> **1–4**† are indeed major volatile products, but has also revealed that in all of the systems studied a second major product could be separated by low-pressure distillation from involatile residues. This second product, accounting for some 25–37% of the total mass of the products, was the unexpected novel fused-ring CB<sub>4</sub>N<sub>5</sub> heterocyclic system **7–10**.

In all of the cases studied (R = Me, Et, Bu<sup>t</sup> or CH<sub>2</sub>F) the ‘carboraza’ (carbon–boron–nitrogen) products **7–10** were colourless liquids that decomposed slowly in moist air. They were characterized by multinuclear NMR, mass and infrared spectroscopy and elemental analyses. Their bicyclic structures and the identities and sites of substituents were deduced from their NMR spectra. Boron-11 NMR studies of **7** showed a group of doublets at δ 35.0, 33.8 and 32.4 and a singlet at δ 25.8 (intensity ratio 3:1) that could be assigned to the three unique BH groups and B<sup>9</sup> (the boron atom common to both rings, with no substituent hydrogen atom) respectively. The carbon-13 and proton NMR spectra of **7** showed peaks for the CHMe and non-equivalent CH<sub>2</sub>Me units as expected.

The <sup>1</sup>H NMR spectra of **7** revealed two of the four CH<sub>2</sub> groups to host diastereotopic protons. This clearly means that the two CH<sub>2</sub> groups at N<sup>1</sup> and N<sup>3</sup> are closer to the centre of asymmetry, *i.e.* the ring carbon, than the other ones.<sup>3</sup> This enables us to distinguish **7** from the other possible isomer with the ring carbon in the 4 position. The structures of **8–10** were deduced similarly from their NMR spectra.

Further support for the structure of **7** which we have been unable to obtain in suitable crystalline form for X-ray crystallographic characterization is shown by proton nuclear Overhauser effect (NOE) and boron IGLO/NMR<sup>4</sup> studies (Fig. 1). The structure of **7** was optimized at the STO-3G level<sup>5</sup> to give the geometry shown in Fig. 2. Using the optimized geometry of **7** as the model, the minimum distances between the methine proton and the methylene protons are 1.99 Å for H<sup>a</sup> and 2.17 Å for H<sup>b</sup>, H<sup>c</sup> and H<sup>d</sup> in agreement with NOE showing the methine

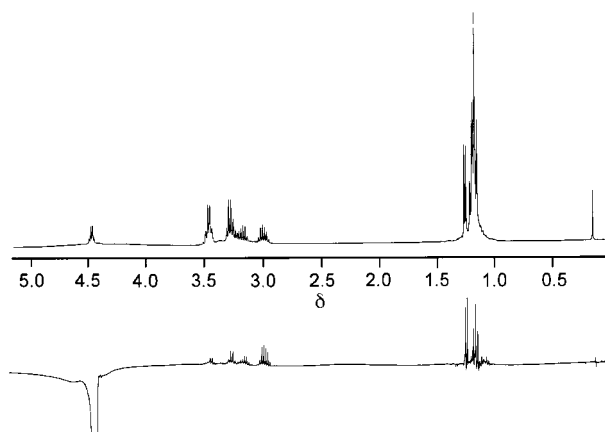

proton to be significantly closer to one methylene proton (H<sup>a</sup>) than the others (H<sup>b</sup>, H<sup>c</sup> and H<sup>d</sup>). The different values of H<sup>a</sup> and H<sup>b</sup> are due to the restriction in the rotation of the ethyl group at N<sup>1</sup> by the ethyl group at N<sup>8</sup> with an hypothetical distance of 3.5 Å between the methyl carbon at N<sup>1</sup> and the methylene carbon at N<sup>8</sup> as the minimum allowed.

† Syntheses of **1–4** and **7–10**. In a typical experiment, B<sub>2</sub>H<sub>6</sub> (5.5 g, 0.25 mol), generated by dripping BF<sub>3</sub>·OEt<sub>2</sub> (50 cm<sup>3</sup>, 0.40 mol) into a solution of NaBH<sub>4</sub> (12.5 g, 0.33 mol) in dry diglyme (2-methoxyethyl ether) (80 cm<sup>3</sup>) over a period of 2 h, was swept in a stream of nitrogen into the nitrile RC≡N (51.3 cm<sup>3</sup>, 1.0 mol) at 60 °C. Distillation through a short column allowed unchanged nitrile and the borazine H<sub>3</sub>B<sub>3</sub>N<sub>3</sub>R<sub>3</sub> **1–4** to be removed separately. Subsequent distillation at <0.1 mmHg (1 mmHg = 133.322 Pa) afforded the carboraza heterocycle **7–10** as a colourless liquid distillate leaving a waxy involatile residue.

When BH<sub>3</sub>·thf [as a molar solution in tetrahydrofuran (thf)] was used as the source of borane, the appropriate volume to generate ultimately a 1:2 molar ratio of BH<sub>3</sub> to RCN was added dropwise to the hot nitrile during 2 h. The volatility of the thf allowed it to be distilled, with unchanged nitrile, from the reaction mixture before the boron-containing products.

1,3,5-Triethylborazine **1**<sup>2</sup> (9.55 g, 36% based on consumed B<sub>2</sub>H<sub>6</sub>), b.p. 154–160 °C. 1,3,6,8-Tetraethyl-2-methyl-1,3,6,8,10-pentaaza-4,5,7,9-tetraboradihydronaphthalene **7** (11.88 g, 36%), b.p. 70–80 °C at 0.05 mmHg (Found: C, 44.7; H, 10.6; N, 26.6%; *M*<sup>+</sup> 260. C<sub>10</sub>H<sub>27</sub>B<sub>4</sub>N<sub>5</sub> requires C, 46.1; H, 10.4; N, 26.9%; *M* 260); δ<sub>B</sub>(164 MHz; solvent CDCl<sub>3</sub>; standard BF<sub>3</sub>·Et<sub>2</sub>O) 35.0 (1 B, d, BH), 33.8 (1 B, d, BH), 32.4 (1 B, d, BH), 25.8 (1 B, s, B<sup>9</sup>); δ<sub>H</sub>(500 MHz; CDCl<sub>3</sub>; SiMe<sub>4</sub>) 4.43 (1 H, s, BH), 4.42 [1 H, q, <sup>3</sup>J(HH) 6, C<sup>2</sup>H], 4.38 (1 H, s, BH), 4.09 (1 H, s, BH), 3.41 [2 H, q, <sup>3</sup>J(HH) 7, CH<sub>2</sub>], 3.41 [1 H, dq, <sup>2</sup>J(HH) 14, <sup>3</sup>J(HH) 7, H<sup>d</sup>/H<sup>q</sup>], 3.23 [2 H, q, <sup>3</sup>J(HH) 7, CH<sub>2</sub>], 3.19 [1 H, dq, <sup>2</sup>J(HH) 14, <sup>3</sup>J(HH) 7, H<sup>c</sup>/H<sup>d</sup>], 3.13 [1 H, dq, <sup>2</sup>J(HH) 14, <sup>3</sup>J(HH) 7, H<sup>b</sup>], 2.95 [1 H, dq, <sup>2</sup>J(HH) 14, <sup>3</sup>J(HH) 7, H<sup>a</sup>], 1.20 [3 H, d, <sup>3</sup>J(HH) 6, C<sup>2</sup>CH<sub>3</sub>], 1.15 [3 H, t, <sup>3</sup>J(HH) 7, CH<sub>3</sub>], 1.12 [9 H, t, <sup>3</sup>J(HH) 7 Hz, 3 CH<sub>3</sub>]; δ<sub>C</sub>(100 MHz; CDCl<sub>3</sub>; SiMe<sub>4</sub>) 69.1 (d, C<sup>2</sup>), 45.3 (t, CH<sub>2</sub>), 44.5 (t, CH<sub>2</sub>), 43.5 (t, CH<sub>2</sub>), 42.2 (t, CH<sub>2</sub>), 26.1 (q, C<sup>2</sup>CH<sub>3</sub>), 20.5 (q, CH<sub>3</sub>), 20.1 (q, 2 CH<sub>3</sub>), 16.6 (q, CH<sub>3</sub>); *m/z* 260 (*M*<sup>+</sup>, 0.8%), 245 (*M* – CH<sub>3</sub>, 100). 1,3,5-Tripentylborazine **2**<sup>2</sup> 32%, b.p. 40–45 °C at 0.05 mmHg. 2-Ethyl-1,3,6,8-tetrapropyl-1,3,6,8,10-pentaaza-4,5,7,9-tetraboradihydronaphthalene **8** 37%, b.p. 120–125 °C at 0.1 mmHg; δ<sub>B</sub> 33.8 (3 B, br, 3 BH), 26.1 (1 B, s, B<sup>9</sup>); *m/z* 330 (*M*<sup>+</sup>, 1.4%), 302 (*M*<sup>+</sup> – C<sub>2</sub>H<sub>5</sub>, 100). 1,3,5-Tri(*tert*-butylmethyl)borazine **3** 63%, b.p. 95–105 °C at 0.08 mmHg; δ<sub>B</sub> 34.9; *m/z* 276 (*M*<sup>+</sup> – CH<sub>3</sub>, 8%), 234 (*M*<sup>+</sup> – C<sub>4</sub>H<sub>9</sub>, 100). 2-*tert*-Butyl-1,3,6,8-tetra(*tert*-butylmethyl)-1,3,6,8,10-pentaaza-4,5,7,9-tetraboradihydronaphthalene **9** 26%, b.p. 145–155 °C at 0.02 mmHg; δ<sub>B</sub> 34.3 (3 B, br, 3 BH), 27.8 (1 B, s, B<sup>9</sup>); *m/z* 471 (*M*<sup>+</sup>, 0.2%), 456 (*M*<sup>+</sup> – CH<sub>3</sub>, 2), 414 (*M*<sup>+</sup> – C<sub>4</sub>H<sub>9</sub>, 100). 1,3,5-Tri(2'-fluoroethyl)borazine **4** 46%; (<sup>1</sup>/<sub>3</sub> scale) b.p. 55–65 °C at 0.04 mmHg; δ<sub>B</sub> 34.3; *m/z* 218 (*M*<sup>+</sup>, 3%), 185 (*M*<sup>+</sup> – CH<sub>2</sub>F, 100). 2-Fluoromethyl-1,3,6,8-tetra(2'-fluoroethyl)-1,3,6,8,10-pentaaza-4,5,7,9-tetraboradihydronaphthalene **10** 28% (<sup>1</sup>/<sub>3</sub> scale; **Caution**: it can decompose spontaneously to a non-volatile polymeric solid during vacuum distillation), b.p. 120–130 °C at 0.04 mmHg; δ<sub>B</sub> 34.6 (3 B, br, 3 BH), 25.6 (1 B, s, B<sup>9</sup>); *m/z* 350 (*M*<sup>+</sup>, 0.8%), 317 (*M*<sup>+</sup> – CH<sub>2</sub>F, 100).

Synthesis of **11**. Compound **7** (2.36 g, 9 mmol) in Et<sub>2</sub>O (100 cm<sup>3</sup>) was treated with MeLi (35 mmol in 30 cm<sup>3</sup> hexane) and heated under reflux for 70 h. Diethyl ether was removed. The product was filtered and distilled to afford a fraction b.p. 140–160 °C at 0.05 mmHg identified as **11**. 2,4,5,7-Tetramethyl-1,3,6,8-tetraethyl-1,3,6,8,10-pentaaza-4,5,7,9-tetraboradihydronaphthalene **11** (2.26 g, 7.5 mmol, 83%); δ<sub>B</sub> 37.8 (1 B, s, BMe), 35.9 (2 B, s, 2 BMe), 29.1 (1 B, s, B<sup>9</sup>); *m/z* 302 (*M*<sup>+</sup>, 0.6%), 288 (*M*<sup>+</sup> – CH<sub>2</sub>, 100).

ORTEP diagram of the molecular structure of 2,2,3,3-tetrakis(benzimidazol-2-yl)quinoxaline. The structure shows a central quinoxaline core with four benzimidazole rings attached at the 2, 3, 7, and 8 positions. Thermal ellipsoids are drawn at the 50% probability level. Displacement ellipsoid coefficients are provided in the table below.

Boron–nitrogen heterocycles incorporating some carbon atoms are also accessible from reactions of organoboranes with nitriles<sup>11</sup> or hydrogen cyanide,<sup>12</sup> though they require higher temperatures or hazardous materials (HCN). Other mixed carbon–boron–nitrogen ring systems are known, including borazarenes containing even numbers of carbon atoms in their rings, though these have normally required multi-step syntheses.<sup>13</sup> The reactions we describe here are the first to provide direct easy access to fused-ring ‘carboraza’ systems from commercially available acyclic precursors.

We are grateful to Dr. A. M. Kenwright, I. H. McKeage and J. M. Say for the high-field NMR spectra and EPSRC for financial support. D. L. Ormsby and Dr. R. Greatrex (School of Chemistry, Leeds) are thanked for the IGLO computations and Dr. C. v. Wüllen (Bochum) for the provision of DIGLO software.

Formation of the carboraza heterocycles **7–10** in these reactions [and in similar reactions at 40–50 °C, or using  $\text{BH}_3 \cdot \text{thf}$  as the source of borane instead of  $\text{B}_2\text{H}_6$ ] is intriguing. Nucleophilic attack by the nitrile nitrogen atom on the co-ordinated nitrile carbon of  $\text{RC}\equiv\text{N}\cdot\text{BH}_3$  or aldimino carbon of  $(\text{RCH}=\text{NBH}_2)_2$  could generate the C–C–N–C–C skeletal unit found as the  $\text{R}-\text{CH}-\text{N}-\text{CH}_2\text{R}$  residue in **7–10** along with C–N bond cleavage. A previous indication that such nitrile coupling and C–N bond cleavage can occur was provided by the isolation of traces of  $\text{B}_2\text{H}_5\text{Net}_2$  **12** from the diborane–acetonitrile reaction.<sup>1</sup>

‡ Calculated NMR chemical shifts [STO-3G/IGLO(DZ)] of the alternative isomer of **7**, where the ring carbon is at the 4 position, are  $\delta$  31.9, 30.4, 27.7 and 21.7.
