Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

Supporting Information Placeholder

ABSTRACT: Cobalt catalysts with electronically enhanced site selectivity have been developed as evidenced by the high *ortho* to fluorine selectivity observed in the C(sp²)-H borylation of fluorinated arenes. Both the air-sensitive cobalt(III) dihydride boryl 4-Me-(ⁱPrPNP)Co(H)₂BPin (**1**) and the air-stable cobalt(II) bis(pivalate), 4-Me-(ⁱPrPNP)Co(OPiv)₂ (**2**) compounds were effective and exhibited broad functional group tolerance across a wide range of fluoroarenes containing electronically diverse functional groups, regardless of the substitution pattern on the arene. The electronically enhanced *ortho* to fluorine selectivity observed with the cobalt catalysts was maintained in the presences of a benzylic dimethylamine and hydrosilanes, overriding the established directing group effects observed with precious metal catalysts. The synthetically useful selectivity observed with cobalt was applied to an efficient synthesis of the anti-inflammatory drug Flurbiprofen.

INTRODUCTION

The direct, selective C-H functionalization of organic molecules in the absence of directing groups is a grand challenge in modern catalysis. Fluorinated arenes are prominent targets given the prevalence of this subunit in pharmaceuticals¹, agrochemicals² and organic materials (Figure 1).³ Efficient methods for the synthesis of *ortho*-fluorinated aryl boronate esters are attractive given the versatility of the boron substituent for elaboration by Suzuki-Miyaura cross coupling, Chan-Lam-Evans coupling, and a host of other methods.⁴

Pharmaceuticals

Agrochemicals

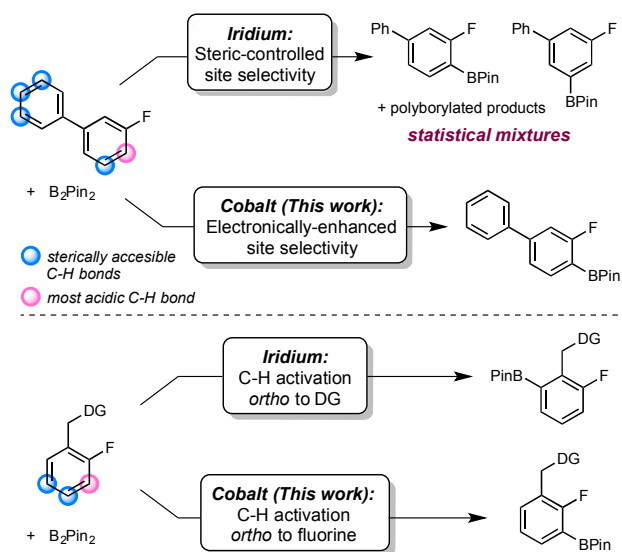

Figure 1. Examples of *ortho*-fluoroaryl motifs in pharmaceuticals and agrochemicals.

Iridium-catalyzed C-H borylation has emerged as one of the most widely-used C-H functionalization methods due to its high efficiency and complementary selectivity to traditional electrophilic aromatic substitution.^{5,6} Iridium complexes containing bipyridine or phenanthroline ligands are the most widely used, mechanistically well understood⁷⁻⁹ and exhibit predictable site selectivity that is typically controlled by the steric accessibility of the C-H bond.

Distortion interaction analysis established that the regioselectivity in these reactions is largely controlled by the interaction of the arene carbon with the iridium catalyst, although fluorinated arenes were not thoroughly addressed in this study.⁹ It is well-established that the C-H bond *ortho* to fluorine in fluoroarenes is more acidic relative to the *meta* and *para* C-H bonds;¹⁰ however, selective, catalytic C-H borylation of this position in the presence of other sterically accessible C-H bonds still remains a challenge.¹¹ Alternative strategies for the preparation of single regioisomers of fluorinated aryl boronate esters have been developed including installation and removal of blocking groups to increase the selectivity of the iridium catalyzed reaction.¹² Use of NHC-^{13a}- and PSiN-ligated platinum catalysts,^{13b} as well as phosphine^{14a}- and POP-supported rhodium catalysts^{14b} have all been explored to increase the *ortho* to fluorine selectivity in fluoroarene borylation. While important advances, the requirement of excess arene, elevated temperatures, and multiple fluorines in the arene substrate detract from the general utility of these methods.^{13,14}

Scheme 1. Cobalt-catalyzed C(sp²)-H Borylation with Enhanced *Ortho* Site Selectivity with Fluoroarenes.

In a recent patent application, specific electron-poor bidentate ligands such as 4,4'-bis(trifluoromethyl)-2,2'-bipyridine (btfbpy) and 4,4',5,5'-tetrakis(trifluoromethyl)-2,2'-bipyridine (ttfbpy) have been claimed to enable selective iridium-catalyzed C-H borylation of 1-chloro-3-fluoro-2-substituted benzenes.¹⁵ Up to 82:18 *ortho* to *meta* selectivity was reported for the iridium-catalyzed C-H borylation of 1-chloro-2,3-difluorobenzene using ttfbpy as the ligand. Monodentate pyridine ligands were also claimed to be effective ligands to achieve high *ortho* to fluorine selectivity in the iridium-catalyzed C-H borylation of 3-fluorotoluene. Specifically, an 82:18 (4.7:1) *ortho* : *meta* selectivity was reported with 2-methoxy pyridine (2-OMe-Py) as the ligand.

First row transition metal catalysts for C-H borylation are attractive not only for potential cost and environmental advantages, but also for the opportunity for new reactivity and selectivity over known precious metal catalysts.¹⁶ Among the base metal examples reported, [(ⁱPrPNP)Co]-based catalysts are the most active for the C(sp²)-H borylation of arenes and heteroarenes.¹⁷ Mechanistic studies support a Co(I)-Co(III) pathway, in which a cobalt(I)-boryl is responsible for C-H activation. Substitution of the 4-position of the pincer prevented catalyst deactivation by C-H borylation of the ligand, and inspired the preparation of improved, second generation 4-methyl and 4-pyrrolidinyl substituted catalysts.¹⁸ With the first generation cobalt alkyl, [(ⁱPrPNP)CoCH₂SiMe₃], unprecedented 89:11 *ortho*:*meta* selectivity for the borylation of fluorobenzene with B₂Pin₂ (Pin = pinacolate) was observed.¹⁷ Here, we describe a more general cobalt-catalyzed method for the *ortho* to fluorine selective borylation of a wide range of fluorinated arenes (Scheme 1). The cobalt pre-catalysts, including an air-stable variant, offer distinct selectivity enhancements over known precious metal catalysts, enabling an efficient synthesis of the anti-inflammatory drug Flurbiprofen.

RESULTS AND DISCUSSION

Synthesis of 4-Me-(ⁱPrPNP)Co(O₂C^tBu)₂ (2). The 4-methyl substituted pincer, 4-Me-ⁱPrPNP was selected for these studies due to its relative ease of synthesis, electron donating properties, and resistance to deactivation by borylation during turnover.¹⁸ The cobalt(III) dihydride boryl (1) and cobalt(II)

bis(pivalate) (2) complexes were used as pre-catalysts (Figure 2). Complex 1 was selected due to the precedent for cobalt(III) precursors as effective pre-catalysts for C-H borylation¹⁸ while complex 2 was prepared due to its relative ease of synthesis and its air-stability. Recent studies from our laboratory¹⁹ and others²⁰ have demonstrated both the air stability and utility of cobalt^{19a-d,20} and nickel^{19e} carboxylates as catalyst precursors.

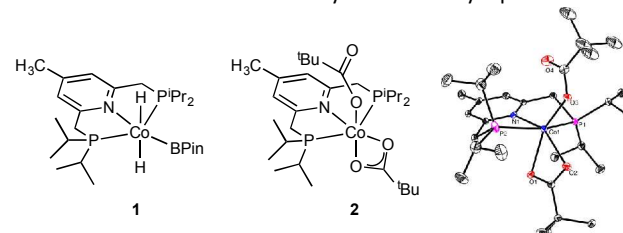

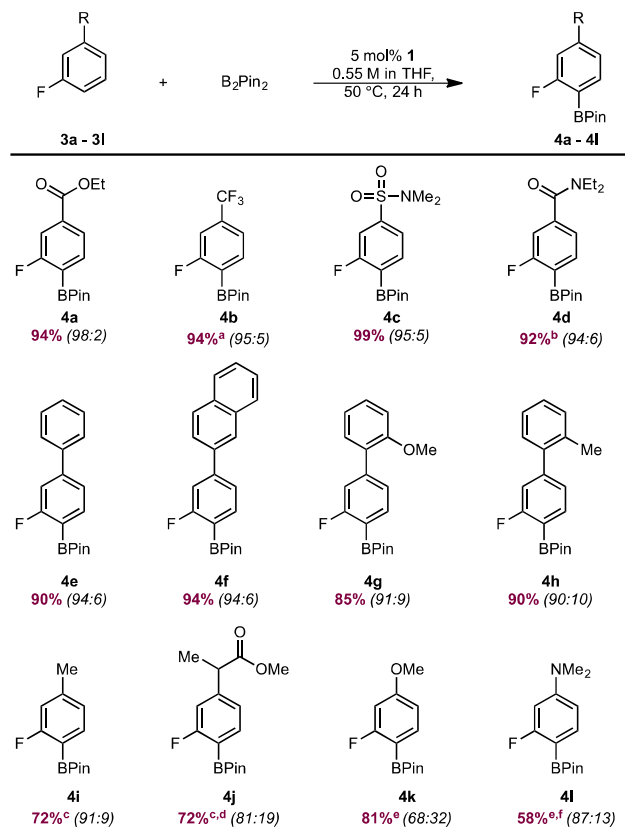

Figure 2. Cobalt pre-catalysts 1 and 2 and solid state molecular structure of 2 at 30% probability ellipsoids. Hydrogen atoms omitted for clarity.

Cobalt complex 2 was synthesized by the straightforward addition of the free ligand to anhydrous cobalt pivalate²¹ and was isolated in 49% yield as a purple powder with an *S* = 3/2 ground state (μ_{eff} = 4.1(1) μ_{B} at 23 °C, solid state). Structural characterization (Figure 2) established a six coordinate cobalt complex with κ^1 and κ^2 carboxylate ligands. A single paramagnetically shifted *tert*-butyl resonance was observed by ¹H NMR spectroscopy, suggesting rapid interconversion of κ^1 and κ^2 carboxylate ligands on the NMR time scale, similar to related pyridine diimine^{19c} and terpyridine cobalt complexes.^{19d,e} It is also possible that the κ^1 and κ^2 forms are indistinguishable by NMR spectroscopy. Compound 2 exhibited excellent bench stability as no change in the ¹H NMR spectrum of the compound was observed after exposure of the solid to air for 5 days (Figure S1).

Substrate Scope Using 1 as a Pre-catalyst. The site selectivity of cobalt catalyzed C(sp²)-H borylation was explored in a variety of arenes with various substitution patterns (Table 1). Pre-catalyst 1 was evaluated initially with a series of 3-substituted fluoroarenes. Efficient borylation was observed over the course of 24 hours at 50 °C with B₂Pin₂. The aryl-boronate products were obtained in high yields and *ortho* to fluorine selectivity with arenes containing ester (4a), trifluoromethyl (4b), sulfonamide (4c), and amide (4d) functional groups. Recrystallization of the regioisomeric mixture of 4d yielded regiochemically pure 4d in 69% isolated yield. With polyaromatic substrates (4e, 4f, 4g, 4h), exclusive borylation of the ring containing the fluorine atom was observed despite the presence of multiple sterically accessible C(sp²)-H bonds. Fluoroarenes containing electron-donating groups (4i, 4j, 4k, 4l) were borylated with reduced *ortho* to fluorine selectivity. These observations support the hypothesis that the site selectivity of the catalytic borylation reaction of fluoroarenes is determined by the relative acidity of the C-H bond in addition to the steric factors that typically dictate selectivity with precious metal catalysts.^{5,6}

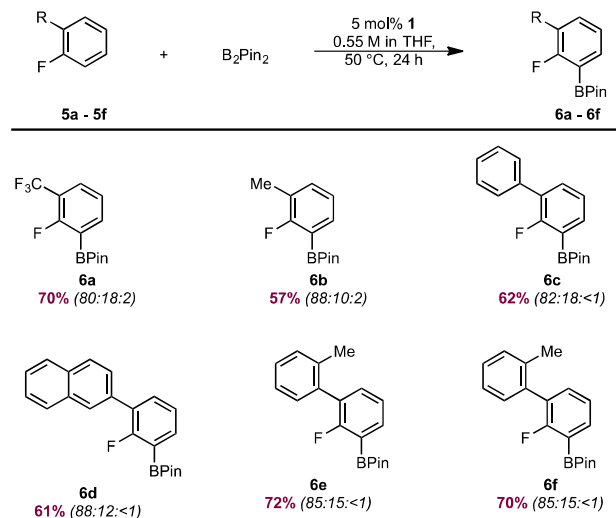

Table 1. Substrate Scope of the *Ortho* to Fluorine C(sp²)-H Borylation of 3-substituted Fluoroarenes Catalyzed by 1.

Reaction conditions: arene (0.55 mmol), B_2Pin_2 (0.55 mmol), **1** (0.0275 mmol, 5 mol%), THF (1 mL), 50 °C. Reported numbers are isolated yields after column chromatography. Numbers in parentheses correspond to the regioselectivities (*ortho*:*meta* ratio) determined by ^{19}F NMR spectroscopy. ^a1 mol% **1**. ^b69% yield (>99:1 *ortho*:*meta*) after recrystallization. ^c48 h. ^d2.74 mmol scale. ^e72 h. ^f25 mol% **1**; 80 °C, 1.1 M in THF; 5 equiv. **3l** was used.

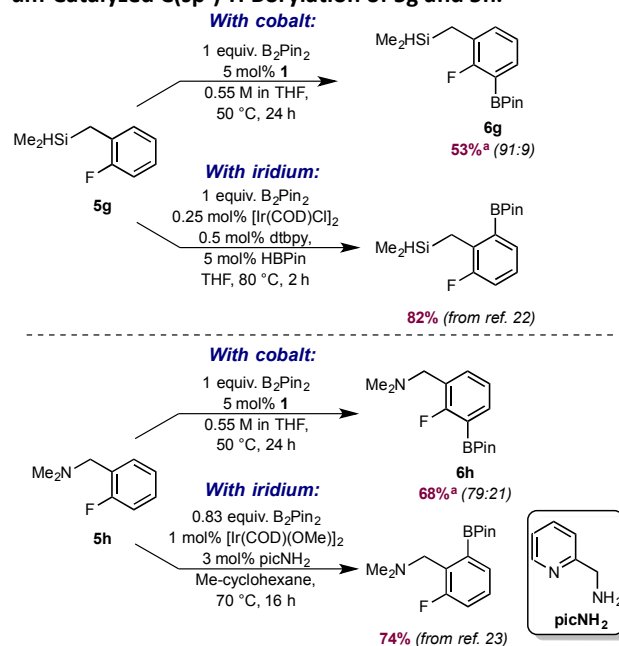

Fluoroarenes containing substituents at the 2-position were also suitable substrates for cobalt-catalyzed borylation (Table 2). With this class of substrates, where three sterically accessible C-H bonds are present, selective borylation of the C-H bond *ortho* to fluorine was observed with negligible borylation of the C-H bond *para* to fluorine. As in the case of 3-substituted fluoroarenes, no polyborylation of the polyaromatic substrates (**6c**, **6d**, **6e**, **6f**) was detected.

Table 2. Substrate Scope of the *Ortho* to Fluorine $C(sp^2)$ -H Borylation of 2-substituted Fluoroarenes Catalyzed by **1.**

Reaction conditions: arene (0.55 mmol), B_2Pin_2 (0.55 mmol), **1** (0.0275 mmol, 5 mol%), THF (1 mL), 50 °C. Reported numbers are isolated yields after column chromatography. Numbers in parentheses correspond to the regioselectivities (*ortho*:*meta*:*para* ratio) determined by ^{19}F NMR spectroscopy.

Scheme 2. Complementary Selectivity in Cobalt and Iridium-Catalyzed $C(sp^2)$ -H Borylation of **5g** and **5h**.

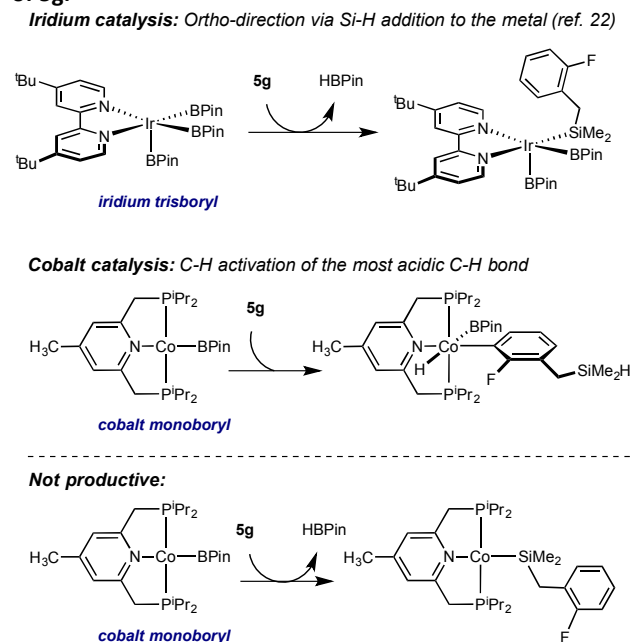

^aReported numbers are combined NMR yield of *ortho* and *meta* monoborylated products (crude mixture) determined by ^{19}F NMR spectroscopy using 4-F-toluene as the internal standard and numbers in parentheses are *ortho*:*meta* ratio.

Fluoroarenes containing a benzylic hydrosilane group and a benzylic dimethylamine, well-known *ortho* directing groups in iridium-catalyzed C-H borylation,^{22,23b} were selectively borylated *ortho* to fluorine rather than *ortho* to these functional groups to yield fluoroarenes **6g** and **6h** (Scheme 2). In iridium catalysis, benzylic hydrosilanes are proposed to direct *ortho*-borylation from formation of a putative iridium bis(boryl) silyl intermediate arising from reaction of the silane S-H bonds with the iridium tris(boryl) followed by selective C-H activation (Scheme 3). If a similar sequence was operative with cobalt, the

intermediate cobalt silyl complex obtained from reaction of **5g** with the cobalt(I) boryl,¹⁸ lacks an additional boryl ligand to promote C-H activation and C-B bond formation and likely accounts for the lack of the directing effect with the first row transition metal. Instead borylation of the most acidic C(sp²)-H bond is observed, consistent with the enhanced electronic selectivity imparted by cobalt.

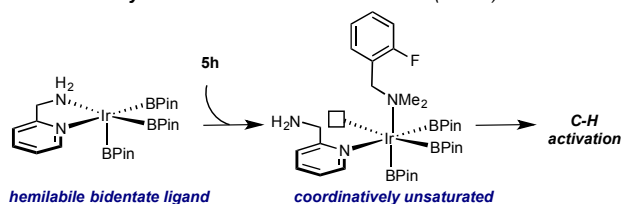

Scheme 3. Proposed Origin of the Complementary Selectivity in Cobalt- and Iridium-Catalyzed C(sp²)-H Borylation of **5g**.

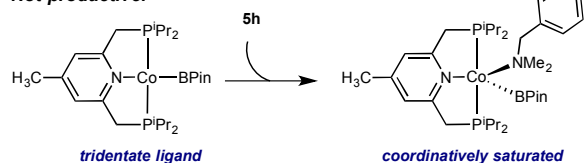

Iridium catalysts containing hemilabile N,N ligands^{23a} promote *ortho*-borylation using a benzylic dimethylamine as a directing group.^{23b} The *ortho* selectivity is proposed to arise from coordination of the [NMe₂] group to the metal followed by dissociation of an amine nitrogen from the supporting N, N chelate, opening a site for C-H activation (Scheme 4).^{23b} With cobalt, the benzylic dimethylamino group has proven ineffective for directing *ortho* selectivity, likely due to the tridentate pincer. While dissociation of one of the phosphine arms is possible, coordination of the amine does not influence the outcome of the C(sp²)-H borylation and the first row metal maintains its preference for the most acidic C-H bond. This outcome arises from reversible coordination of the amine without concurrent C-H activation, perhaps due to relative saturation in the intermediate, or lack of coordination of the [NMe₂] group.

Scheme 4. Proposed Origin of the Complementary Selectivity in Cobalt- and Iridium-Catalyzed C(sp²)-H Borylation of **5h**.

Iridium catalysis: *Ortho*-direction via coordination (ref. 23)

Not productive:

Exclusive *ortho* to fluorine selectivity was observed in the C(sp²)-H borylation of 4-substituted fluoroarenes containing a variety of functional groups (Table 3). These findings are similar to what was observed in the iridium-catalyzed C-H borylation to furnish **8d**²⁴ and **8f**²⁵, with slightly higher *ortho* to fluorine selectivity for **8f**. As with 3- and 2-substituted polyaromatic fluoroarenes, exclusive borylation of the fluorine-containing ring was observed in *p*-fluorobiphenyl (**7e**) to yield a 94:6 ratio of mono:diborylated products, where the -BPiPr groups are located *ortho* to fluorine.

Reaction conditions: arene (0.55 mmol), B₂Pin₂ (0.55 mmol), **1** (0.0275 mmol, 5 mol%), THF (1 mL), 50 °C. Numbers in parentheses are isolated yields after column chromatography. ^{a,c,d}Isolated as a 91:9^a, 93:7^c, and 94:6^d mixture of mono and diborylated products. Reported numbers correspond to % yield of monoborylated product. ^b2 equiv. B₂Pin₂ was used. ^eNMR yield of **8f** determined by ¹⁹F NMR spectroscopy using 4-F-toluene as the internal standard.

Unfortunately, fluoroarenes containing bromo- and chloro substituents (**3m**, **3n**, and **3o**) were incompatible with cobalt-catalyzed C(sp²)-H borylation (Figure 3). Performing a stoichiometric reaction between **1** and **3n** resulted in immediate formation of (4-Me-ⁱPr)PNP)CoCl (**9**).¹⁸ Reaction of 3-fluorotoluene (**3i**) with B₂Pin₂ at 50 °C (0.55 M in THF) in the presence of 5 mol% of **9** resulted in no product formation at 24 hours of heating., establishing formation of **9** as a catalyst deactivation pathway.

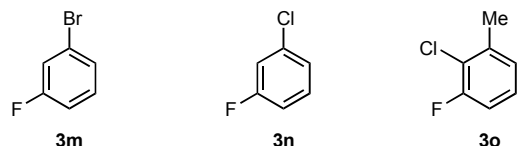

Figure 3. Fluoroarenes incompatible with cobalt-catalyzed C(sp²)-H borylation.

Comparisons with Iridium Catalysts. The unique selectivity of the cobalt catalyst was confirmed by direct comparison of the activity and selectivity of **1** to iridium catalysts. A variety of 3-substituted fluoroarenes were selected as substrates given the availability of two sterically accessible but electronically differentiated C(sp²)-H bonds (Table 4). Four different reaction conditions were selected for the iridium cases to ensure fair and representative comparisons between the precious and earth abundant transition metal catalysts. Conditions A and B employ the state-of-the-art and widely used [Ir(COD)OMe]₂/dtbpy (dtbpy = 4,4'-di-*tert*-butyl-2,2'-bipyridine)^{6c} using the optimized conditions for cobalt (Conditions A) and also using conditions reported in the literature (Conditions B).²⁶ The other two conditions employed [Ir(COD)OMe]₂ in combination with 4,4'-bis(trifluoromethyl)-2,2'-bipyridine (Conditions C) and 2-methoxy

oxypyridine (Conditions D), ligands claimed to enhance *ortho* to fluorine selectivity in the iridium-catalyzed C-H borylation of 1-chloro-3-fluoro-2-substituted benzenes and 3-fluorotoluene.¹⁵ In all cases, iridium catalysis proved significantly less selective for the borylation of 3-substituted fluoroarenes with B₂Pin₂ as nearly statistical distributions of *ortho* and *meta* borylated products were observed. The higher activity of the [Ir(COD)OMe]₂/dtbpy catalyst mixture compared to cobalt is highlighted in the borylation of the electron-rich fluoroarene **3l**. For Conditions A and B, complete conversion of arene was observed in the borylation of **3a**, **3j**, and **3k** with iridium; however, a lower combined NMR yield of the desired monoborylated products was obtained presumably due to competing reactions of the ester (**3a**, **3j**) and the methoxy (**3k**) groups. The borylation of polyaromatic fluoroarenes (**3e**²⁷ and **3f**) highlights the advantages of the cobalt catalyst. With iridium, complex mixtures of products were observed, a result of competing borylation of the other sterically accessible C-H bonds in the adjacent aryl ring (see Figures S6 and S7). With cobalt, however, the selectivity is high and only borylation of the fluorinated ring was observed, furnishing monoborylated products **4e** and **4f** in 90% and 94% combined yields, respectively, with 96:4 *ortho* to *meta* selectivity in both cases. Using the electron-poor ligand, 4,4'-bis(trifluoromethyl)-2,2'-bipyridine, for iridium (Conditions C) resulted in an enhancement of *ortho* to fluorine selectivity for arenes **3a**, **3e**, **3f**, **3k**, and **3l** relative to the [Ir(COD)OMe]₂/dtbpy mixture, however, the selectivities were still inferior to that observed with cobalt. Finally, the use of 2-methoxypyridine as the ligand for the iridium-catalyzed reaction (Conditions D) resulted in poor conversion and nearly statistical distributions of *ortho* and *meta* borylated products (Table 4).

Reactions were run with equimolar amounts of **3b** and B₂Pin₂ on a 0.55 mmol scale. ^aIsolated yield after column chromatography. ^b*Ortho* : *meta* ratio determined by ¹⁹F NMR. ^c20 mol% of HBPIn added. ^dRun in THF-d₈. ^e% Conversion determined by ¹⁹F NMR. ^fPre-catalyst exposed to air for 1 hr. ^gRun on a 5.5 mmol scale. ^hPre-catalyst exposed to air for 14 days. ⁱ% Conversion determined by GC. ^j4 mol% of HBPIn added.

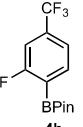

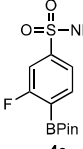

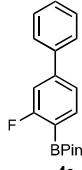

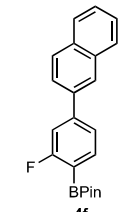

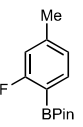

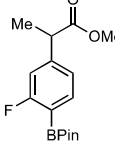

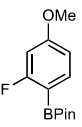

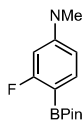

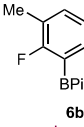

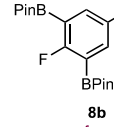

Catalytic C-H borylation was accomplished using **2** and B₂Pin₂ at 50 °C (entry 5), although an approximate 12-hour induction period was observed. Addition of HBPIn as an activator^{19a} produced comparable activity to **1** (entry 2). Pre-catalyst **2** was exposed to air for one hour without any measurable erosion of activity or selectivity (entry 3). At 80 °C, however, comparable activity as well as selectivity with **1** was achieved with **2** (entries 6 and 7) without the need for an external activator. The reaction was successfully scaled to 5.5 mmol using only 1 mol% of **2** to generate the desired *ortho*-fluoroboronate ester **4b** in 94% isolated yield with 93% regiochemical purity (entry 7). Complete conversion of the arene was observed (92:8 *ortho* to *meta* selectivity) when the reaction was carried out at 80 °C using 1 mol% of pre-catalyst **2** that was exposed to air for 14 days, albeit with the requirement of 4 mol% of HBPIn as an activator (entries 8 and 9). Using anhydrous cobalt (II) pivalate as the pre-catalyst resulted in no reaction, highlighting the necessity of the bis(phosphine)pyridine ligand for the C-H borylation reaction (entry 4).

The borylation of a variety of fluoroarenes with different functional groups and substitution patterns was explored using the optimized conditions for arene **3b** with complex **2** as the

pre-catalyst. The activity and selectivity with **2** proved general among a range of fluorinated arenes as high isolated yields and *ortho* to fluorine selectivity were observed regardless of the substituent on the arene and its substitution pattern (Table 6). As with **1**, exclusive *ortho* to fluorine borylation was observed with polyaromatic substrates **4e** and **4f**.

Table 6. Substrate Scope of the *Ortho* to Fluorine C(sp²)-H Borylation of Fluoroarenes Catalyzed by the Air-stable Pre-catalyst **2.**

Application of Cobalt-Catalyzed C(sp²)-H Borylation to the Synthesis of Flurbiprofen. The utility enabled by the increased site selectivity of the cobalt-catalyzed C(sp²)-H functionalization was applied to the total synthesis of the anti-inflammatory drug Flurbiprofen (Scheme 5). Fluoroarene **3j** was prepared by slightly modified procedure from that reported by Durandetti.²⁸ Cobalt-catalyzed *ortho* to fluorine selective C-H borylation of **3j**, followed by Suzuki-Miyaura cross coupling with phenyl bromide, and ester hydrolysis then afforded Flurbiprofen, **11**, in 33% overall yield from commercially availa-

ble **10** with 84% regiochemical purity. Thus, our cobalt-catalyzed method enables a four-step synthesis, streamlined from the eight-step route reported previously²⁹ and highlights the utility of regioselective C-H functionalization in synthetic applications.

Scheme 5. Application of *Ortho* to Fluorine Selective C-H Borylation to the Synthesis of Flurbiprofen (**11**).

Reagents and conditions: (a) Methyl-2-chloropropionate (5.2 equiv.), Mn powder (6 equiv.), TFA (30 μ L), (bpy)NiBr₂ (7 mol%), DMF, 50 $^{\circ}$ C, 16 h; (b) B₂Pin₂ (1 equiv.), **1** (5 mol%), THF, 50 $^{\circ}$ C, 48 h; (c) PhBr (1.1 equiv.), Pd(dppf)Cl₂ (5 mol%), K₂CO₃ (4 equiv.), THF/H₂O (20 : 1), 50 $^{\circ}$ C, 16 h; (d) NaOH (5 equiv.), THF/H₂O (1:1), 90 $^{\circ}$ C, 24 h, then 12 M HCl. Reported numbers are isolated yields after column chromatography. Regioselectivities were determined by ¹⁹F NMR spectroscopy. Overall yield of Flurbiprofen (**11**) is corrected for the *meta*-phenylated regioisomer.

CONCLUSIONS

An efficient, highly *ortho* to fluorine selective cobalt-catalyzed method for the C(sp²)-H borylation of fluorinated arenes has been developed. An air stable, pincer-ligated cobalt(II) bis(pivalate) was synthesized in a single step from the free ligand and appropriate cobalt precursor and was effective for catalytic C(sp²)-H functionalization of electronically diverse substrates regardless of the substitution pattern on the arene. Common directing groups in iridium-catalyzed C-H functionalization such as a benzylic dimethylamino substituent or a hydridosilane did not alter the electronically enhanced site selectivity of the cobalt catalyst, highlighting the complementarity of earth abundant and precious metal catalysts. The improved regioselectivity of the cobalt catalyzed C(sp²)-H borylation was applied to a streamlined synthesis of the anti-inflammatory drug, Flurbiprofen. These studies represent one of the rare examples of selective C-H functionalization that in the absence of directing groups, offers new opportunities for reaction development and applications in synthesis.

Notes

The authors declare the following competing financial interests(s): J.V.O. and P.J.C. are inventors on U.S. Patent Application 61/913,522 (Filed: December 9, 2014, Published: June 18, 2015).

ACKNOWLEDGMENT

J.V.O. acknowledges the 2015 Howard Hughes Medical Institute International Student Research Fellowship and the 2016 Harold W. Dodds Honorific Fellowship (awarded by the Graduate School at Princeton University). M.J.B. thanks the Natural Sciences and Engineering Research Council of Canada for a pre-doctoral fellowship (PGS-D). We also thank AllyChem for a generous gift of B₂Pin₂.

(24) In a study that compares the regioselectivities of Rh-catalyzed C-H silylation and Ir-catalyzed C-H borylation, the C-H borylation reaction of *p*-fluoro-toluene (**7d**) with iridium was reported to undergo exclusive *ortho* to fluorine borylation. See Cheng, C.; Hartwig, J. F. *Science* **2014**, *343*, 853.

(25) The iridium-catalyzed C-H borylation of *p*-fluoro-trifluoromethoxy benzene (**7f**) resulted in *ortho* to fluorine borylation with 97% selectivity. See Batool, F.; Parveen, S.; Emwas, A.-H.; Sioud, S.; Gao, X.; Munawar, M. A.; Chotana, G. A. *Org. Lett.* **2015**, *17*, 4256.

(26) Liskey, C. W.; Liao, X.; Hartwig, J. F. *J. Am. Chem. Soc.* **2010**, *132*, 11389.

(27) The iridium-catalyzed reaction of **3e** using conditions reported in reference 26 was carried out but with only 0.5 equiv of B₂Pin₂ to ensure that no excess boron reagent is present after consumption of arene (Conditions E). A higher combined NMR yield (38%) of the desired monoborylated products was obtained under these conditions; however, polyborylation was still observed.
