electrophilic warheads in covalent protein inhibitors. Conversely, the S(VI) aza-isosteres thereof, vinyl sulfoximines and sulfonimidamides, are far less studied and have yet to be applied to the field of protein bioconjugation. Herein, we report a range of different synthetic methodologies for constructing vinyl sulfoximine and vinyl sulfonimidamide architectures that allows access to new areas of electrophilic chemical space. We demonstrate how late-stage functionalization can be applied to these motifs to incorporate alkyne tags, generating fully functionalized probes for future chemical biology applications. Finally, we establish a workflow for determining the absolute configuration of enantioenriched vinyl sulfoximines and sulfonimidamides by comparing experimentally and computationally determined electronic circular dichroism spectra, enabling access to configurationally assigned enantiomeric pairs by separation.

INTRODUCTION

Sulfoximines and sulfonimidamides, the mono aza-analogues of sulfones and sulfonamides, respectively, are gaining traction as valuable pharmacophores in medicinal chemistry (Figure 1a).^{1,2} Architecturally, these motifs carry asymmetry at the tetrahedral sulfur center, offer hydrogen-bond acceptor and donor functionalities for NH derivatives, and afford new vectors along which to generate structural complexity. Bioactive sulfoximines date back to the discovery of methionine sulfoximine, which was later discovered to be a prodrug inhibitor of glutamine synthetase.³ More recently, new synthetic methodologies have facilitated the incorporation of sulfoximine and sulfonimidamide motifs into drug discovery programs, through which their high chemical and stereochemical stability as well as favorable physicochemical properties have been uncovered.⁴ Indeed, three sulfoximine compounds have entered clinical trials in recent years, with their desirable drug metabolism and pharmacokinetics (DMPK) profiles being cited as key triggers for candidate selection.

Vinyl sulfones and sulfonamides are well-characterized electrophiles and have been extensively utilized as reactive warheads in protein-targeted covalent probes.⁶ For example, substituted vinyl sulfones are found in cysteine-targeting covalent cathepsin inhibitors,⁷ terminal vinyl sulfones have been used in lysine-targeting cyclin-dependent kinase 2 (Cdk2) inhibitors,⁸ and terminal vinyl sulfonamides have

been employed to target cysteine residues on a variety of proteins including mitogen-activated protein kinase 1 (ERK2),⁹ mutant KRas(G12C),¹⁰ Bruton's tyrosine kinase (BTK),¹¹ and ubiquitin-specific protease 7 (USP7)¹² (Figure 1b). Synthetic routes to these scaffolds are well established, and probe specificity is engineered by installation of pharmacophores that bind the target protein and orientate the electrophile to react with a nearby nucleophilic amino acid.¹³

We speculated that vinyl sulfoximines and sulfonimidamides could similarly act as protein reactive warheads in covalent probes.¹⁴ The value of these aza-analogues compared to the established vinyl S(VI) electrophiles would arise from their ability to offer alternative hydrogen-bonding architectures, additional vectors for pharmacophore incorporation, and likely different reactivity profiles. Moreover, the new nitrogen center offers a convenient handle for the attachment of chemical biology functionalities, such as alkynes and fluorophores, to generate fully functionalized probes.¹⁵ As these derivatives are chiral at sulfur, they present increased complexity and potential

complementarity as probes. A recent work from Cravatt has demonstrated the value of using stereochemically paired fully functionalized probes in the context of proteomic screening, offering an internal control for nonspecific protein binding.¹⁶ More broadly, electrophilic fragments are now routinely screened to identify starting points for covalent probes, and

novel electrophilic functionalities are desirable to expand the diversity of covalent fragment libraries.^{17,18}

Over the last 30 years, β -substituted (*E*)-vinyl sulfoximines have been prepared by a variety of approaches utilizing carbonyl addition and then β -hydroxy activation/elimination,¹⁹ Peterson olefination,²⁰ and Horner–Wadsworth–Emmons Scheme 2. Synthetic Methods Described in this Work to Access Vinyl Sulfoximines and Sulfonimidamides

(HWE) olefination²¹ (Scheme 1). More recently, Arvidsson reported an improved HWE sequence that is both high yielding and protecting group free.²² These methodologies demonstrate the chemical stability and tractability of the vinyl sulfoximine motif, and one such recent study has given rise to the first examples of bioactive vinyl sulfoximines that are thought to activate the transcription factor nuclear factor erythroid 2-related factor 2 (Nrf2), although a covalent mechanism of action was not proposed.²³ However, these synthetic routes have clear limitations; they generally utilize multiple-step sequences that are reliant on the use of hydrazoic acid or O-(mesitylenesulfonyl)hydroxylamine (MSH) for sulfoxide imidation, both of which are known for their thermal instability.^{24,25} There are very few examples of terminal vinyl sulfoximines or enantioenriched vinyl sulfoximines. Moreover, the first two examples of vinyl sulfonimidamides were only reported very recently,²⁶ despite the prevalence of the analogous vinyl sulfonamides, which we attribute to the historically limited synthetic methodology regarding sulfonimidamides.

It is notable that in recent years the methods for sulfoximine and sulfonimidamide syntheses have developed considerably.²⁷⁻²⁹ In our groups, we have developed a safe and effective method for the NH transfer to sulfoxides to form sulfoximines using ammonium carbamate and (diacetoxy)iodobenzene.³⁰ Similarly, we and others have developed a onepot oxidation and imidation protocol for the direct conversion of sulfides to sulfoximines.^{31,32} Stockman and Lücking established a related process for the preparation of sulfonimidamides from sulfinamides.³³ We have developed the synthesis of sulfonimidamides from sulfenamides by NH and O transfer.³⁴ It is notable that using this NH-transfer methodology, the reaction of phenylvinylsulfoxide was effective in generating phenylvinyl sulfoximine, although in moderate yield (54%).³⁰ However, the corresponding method from the sulfide was ineffective (14% yield for phenylvinyl sulfide),^{31a}

presumably due to the instability of terminal vinyl sulfides to acid. Improved methods that expand the diversity of accessible products, minimize the use of dangerous reagents and enable the synthesis of fully functionalized probes for future chemical biology investigations would be of considerable interest.

Here, we report the development of new and improved synthetic routes for the preparation of vinyl sulfoximines, exploiting recent developments in the synthesis of aza-S(VI) derivatives. Three orthogonal routes to access terminal and substituted vinyl NH-sulfoximines are investigated, including highly enantioenriched examples (Scheme 2). Furthermore, we report some of the first examples of vinyl NH-sulfonimidamides. These studies considerably extend the scope of the hypervalent iodine-mediated NH-transfer methods and provide a comparison of available routes, highlighting strategies for different substitution patterns. A simple propargylation reaction to convert these products into fully functionalized probes is demonstrated. Finally, we generate stereochemically paired vinyl sulfoximine and sulfonimidamide derivatives, by late-stage chiral separation, and establish a method for their configurational assignment by combining density-functional theory (DFT) calculations and circular dichroism (CD). These approaches allow access to a range of stereochemically defined structures of interest as probes.

RESULTS AND DISCUSSION

Substituted Vinyl (E)-Sulfoximines from Methyl Sulfides and Sulfoxides. Our initial investigations focused on the established HWE approach to vinyl sulfoximine synthesis but commencing from simple sulfides and applying recent methods for NH transfer, using (diacetoxy)iodobenzene and ammonium carbamate, to improve the efficiency and safety.^{31a} Accordingly, methyl sulfides **1a** and **1b** were converted into the corresponding *N*H-sulfoximines **2a** and **2b** in very good yields (Scheme 3a). After *tert*-butyldiphenylsilyl (TBDPS) protection of the sulfoximine nitrogen to

Scheme 3. Synthesis of Substituted (E)-Vinyl Sulfoximines from (a) Methyl Sulfides and (b) Enantioenriched Methyl Sulfoxides

give intermediates 3a and 3b, a one-pot HWE procedure was implemented using a range of aldehyde coupling partners to furnish NTBDPS-protected vinyl sulfoximines 4a-g. Finally, TBDPS deprotection with tetra-*n*-butylammonium fluoride (TBAF) afforded vinyl NH-sulfoximines 5a-g. Both aromatic and aliphatic aldehydes gave similarly high yields for the two steps (5a and 5b). Incorporation of an alkyne functionality was well tolerated (5c and 5e), which is encouraging for the potential to generate future fully functionalized probes. The method also performed well using the more electron-rich anisole-derived sulfoximine (5e-g) and using heteroaromatic aldehydes (5d, 5f, 5g).

Stereochemically enriched sulfoximines are finding increasing utility in drug discovery and asymmetric synthesis but represent synthetically challenging targets.^{4,5,35} Application of an analogous synthetic sequence to enantioenriched sulfoxides (S)-6 and (R)-6 using 4-ethynylbenzaldehyde furnished products (S)-5h and (R)-5h, respectively, with retention of the configuration at sulfur and without loss of enantiomeric excess (ee) (Scheme 3b).³⁰ The stereospecificity of this route and configurational stability of the intermediates and products

are encouraging for the design of future stereochemically defined vinyl sulfoximines. Indeed, powerful methods are well established for the enantioselective oxidation of unsymmetrical methyl sulfides,³⁶ which could be combined with this HWE route to provide access to a broad range of enantioenriched vinyl sulfoximines. By incorporating alkyne functionalities into (*S*)-**Sh** and (*R*)-**Sh**, these structures represent the first example of stereochemically paired fully functionalized vinyl sulfoximine probes.

Substituted (E)-Vinyl Sulfoximines via Alkyne Hydrothiolation. Next, we sought to develop a more efficient route to vinyl sulfoximines to expand the product scope and notably avoid the use of protecting groups and possible regiochemical ambiguity in the deprotonation step of dialkyl sulfoximines. We anticipated that direct oxidation/imidation of vinyl thioethers would be the most direct path. A range of metalcatalyzed alkyne hydrothiolation reactions have been developed that facilitate the synthesis of branched,^{37,38} linear (*E*)vinyl thioethers,³⁹ or linear (*Z*)-vinyl thioethers⁴⁰ in high selectivity. For this study, we were interested in linear (*E*)-vinyl sulfoximines and applied a Wilkinson's catalyst-mediated alkyne thiolalkyation methodology reported by Love, which gives high levels of stereocontrol using 1,2-dichloroethane (DCE) as the solvent.⁴¹ The (*E*)-vinyl thioether products **9** were then converted to the corresponding (*E*)-vinyl sulfoximines **10** using our NH/O-transfer method (Scheme 4).^{31a} This two-step sequence provided efficient access to a diverse range of vinyl sulfoximines in good to excellent yields,

tolerating silyl (10a, 10b), aryl (10c-e), and alkyl (10f) alkynes in combination with aryl (10a, 10c, 10d, and 10f) and alkyl (10b and 10e) thiols. The success of this methodology for alkyl thiols is particularly exciting since access to such products by HWE chemistry is challenging. Indeed, the incorporation of an aryl bromide containing alkyne (10e) and thiol (10d) will enable elaboration of these scaffolds in multiple vectors using transition-metal-catalyzed coupling chemistry. Pleasingly, we were also able to remove the Boc protection group from 10f to afford amine 10g, offering a useful handle for functionalization at the amine.

Terminal Vinyl Sulfoximines via Alcohol Elimination. An alternative synthetic approach was needed to access terminal vinyl sulfoximines. We implemented a two-step sequence based on the controlled activation and elimination of β -hydroxyethyl sulfoximines (Table 1). β -Hydroxy thioethers 11a-d were converted to the corresponding sulfoximines 12a-d in fair-to-excellent yields. Treating alcohols 12a-d with a slight excess of methanesulfonyl chloride and base led to activation and elimination of the alcohol to give the desired NH vinyl sulfoximines 13a-d. The methodology is suitable for producing aromatic (13a and 13b), heteroaromatic (13c), and alkyl (13d) vinyl sulfoximines. The mesylation step generally proceeded with good O/N chemoselectivity; however, we were additionally able to isolate the N-mesyl vinyl sulfoximines in some cases (14a and 14d) as side products. We anticipate that the N-mesyl vinyl sulfoximines would be more electrophilic and reactive than the NH analogues and may represent an interesting new class of electrophile in their own right.

Terminal Vinyl Sulfonimidamides via Alcohol Elimination. We envisioned that an analogous β -hydroxyethyl activation/elimination strategy could be implemented to generate vinyl sulfonimidamides by combining it with our sulfenamide oxidation/imidation method.³³ Accordingly, phenyl piperidine (15a) was treated with tetrahydropyranyl (THP)-protected β -hydroxyethyl disulfide (16) and silver nitrate to generate the corresponding sulfenamide (Scheme 5). The inclusion of Et₃N, in modified conditions, gave improved results by reducing the acidity of the reaction. The sulfenamide was then simultaneously imidated and oxidized using ammonium carbamate and iodosylbenzene to give the THPprotected β -hydroxy sulfonimidamide 17a in 57% yield over two steps. After THP deprotection, mesylation and in situ elimination afforded the desired vinyl sulfonimidamide 18a in 46% over two steps. Notably, the mesylation reaction proceeded with excellent O/N chemoselectivity for the alcohol over the sulfonimidamide. This novel class of electrophile was stable toward silica gel chromatography and showed no noticeable degradation when stored at -20 °C in dimethyl sulfoxide (DMSO) over 6 months. To further exemplify the methodology, we synthesized three additional vinyl sulfonimidamides 18b-d. Starting with racemic 1-methyl-3-phenylpiperazine 16b gave vinyl sulfonimidamide 18b (diastereomer ratio (dr) 1:2). Encouragingly, the reaction sequence was successful with nortriptyline 15c, demonstrating that bioactive motifs can also be converted into vinyl sulfonimidamides. This route has delivered some of the first examples of a chemical motif that has significant potential for future probe design.

N-Propargylation of Vinyl Sulfoximines and Sulfonimidamides. The incorporation of alkyne tags onto small molecules is a highly valuable transformation that enables chemical biology experiments such as activity-based protein profiling and fluorescence microscopy.⁴² In the context of covalent protein targeting probes, the addition of an alkyne tag generates a fully functionalized probe that facilitates visualization and quantification of target engagement.¹⁵ The majority of the previously established covalent warheads do not possess convenient chemical handles for attachment of alkyne tags.^{14b} As such, the design of fully functionalized probes often requires preinstallation of the alkyne handle into the pharmacophore, which can be synthetically challenging.⁴³ Therefore, a general method for late-stage propargylation of small molecules would present significant benefits and opportunities to chemical biologists.

Functionalization, including propargylation, of sulfoximine-NH groups has been widely reported, though for sulfonimidamides much less so.^{44–46} Vinyl sulfoximines and sulfonimidamides are electrophilic in nature, which raises potential reaction compatibility concerns. Pleasingly, however, a diverse range of vinyl sulfoximines and sulfonimidamides could be efficiently propargylated using sodium hydride and propargyl

bromide (Scheme 6). Terminal (19a), substituted (19b and 19c), and heteroaromatic (19d) vinyl sulfoximines as well as tertiary amines-containing vinyl sulfonimidamides (19e, 19f) and bioactive-pharmacophore containing vinyl sulfonimidamide (19g) were all well tolerated.

Configurational Assignment of Enantioenriched Vinyl Sulfoximines and Sulfonimidamides. The binding between proteins and chemical probes often exhibits discriminatory affinity for different stereoisomers. Indeed, the clinical candidate sulfoximine inhibitors roniciclib, atuveciclib, and ceralasertib are all enantiopure.⁵ Therefore, the development of future probes relies on both access to enantioenriched vinyl sulfoximines and sulfonimidamides and the ability to assign their absolute configuration. Through the HWE reaction sequence, highly enantioenriched vinyl sulfoximines (S)-5h and (R)-5h (Scheme 3b) were prepared with a synthetically defined configuration. However, the other synthetic routes to vinvl sulfoximines and sulfonimidamides described herein generate racemic products with respect to the chiral sulfur center. Chiral separation, typically conducted by high-performance liquid chromatography (HPLC) or supercritical fluid chromatography (SFC), offers an alternative method for accessing enantioenriched products and has been highly successful with regard to the production of enantiopure sulfoxide drugs.^{47,48} The value of such separation is dependent on the reliable assignment of absolute configuration, which is typically accomplished by X-ray crystallography,⁴⁹ NMR,⁵⁰ or computational and experimental circular dichroism.⁵¹ Electronic circular dichroism (ECD) is among the most versatile of these techniques and has previously been successfully applied to the stereochemical assignment of sulfoxide drugs and sulfonimidamides.⁵²⁻⁵⁴ To establish whether ECD could be reliably applied to the configurational assignment of vinyl sulfoximines and sulfonimidamides, we first investigated whether quantum mechanical calculations could predict the experimentally observed ECD spectrum for (R)-5h with high confidence.

A conformational search (see the Supporting Information) was performed on the vinyl sulfoximine unit using the B3LYP

functional and the 6-31G* basis set. The low-energy conformers (within 3 kcal/mol of the lowest) were further optimized using cam-B3LYP/6-311++g(d,p) in a conductorlike polarizable continuum model (CPCM) of acetonitrile. We identified four minimum energy conformers of (R)-5h that are significantly populated at ambient temperature (Figure 2a). In the two lowest energy conformers (3 and 1), the vinyl group eclipses the S=O bond, with the two structures varying in the orientation of the NH group. Conformers 15 and 13, which are slightly higher in energy, have the vinyl group eclipsing the S= N bond. The electronic transitions of each conformer of (R)-5h were then calculated, and the UV-vis and ECD spectra were simulated and summed according to their Boltzmann weighting (Figure 2b). It should be noted that the calculated ECD spectra of conformers 3 and 1 were similar to each other in the experimental range (190-340 nm), while the calculated spectra of conformers 13 and 15 were also similar to each other, but with the significant peaks being opposite in sign to those of 3/1. The weighted ECD spectrum is therefore sensitive to the relative conformer energies at the vinyl-S=O dihedral. We then measured the ECD and UV-vis spectra of (R)-5h in acetonitrile experimentally and compared them to the calculated spectra using SpecDis, a dedicated software package for comparing ECD/UV spectral similarity.⁵⁵ Aligning the UV-vis spectra required a 11 nm positive shift correction factor of the calculated spectrum, giving good spectral matches that are characterized by a sharp peak at 197 nm and a broad peak between 270 and 320 nm. Applying the same 11 nm correction factor to the calculated ECD spectrum gave excellent correlation with the experimental ECD, defined by a trough between 200 and 217 nm, a double peak between 217 and 256 nm, and a second trough between 256 and 316 nm. To quantify the ECD spectral match, we applied similarity factor analysis, which gave an 80.7% match for the experimental (R)-5h ECD spectrum with the calculated (R)-5h spectrum but only a 0.7% match with the calculated (S)-5h spectrum. The resulting δ score of 80.0% represents a high confidence assignment and validates that this workflow is reliable and should be suitable for assigning the configuration

of vinyl sulfoximines and sulfonimidamides with unknown stereochemistry.

Next, we selected three compounds 10g, 19g, and 19f for chiral separation, which was performed using the automated HPLC/SFC condition screening system at Reach Separations,⁵⁶ and de novo configurational assignment by ECD using the same modeling workflow and parameters as described for (R)-5h (Table 2). Chiral separation of 10g, where the carbon stereocenter is synthetically defined as (S), gave two diastereoisomers 10g-A and 10g-B as neutral amines. ECD calculation for 10g is challenging because of the presence of the second stereocenter and the conformational flexibility of the acyclic allylic amine. We examined two approaches to simplify this problem. In the first, we used a single fixed, lowenergy conformation of the vinyl amine portion appended to the four conformers of the allylic sulfoximine unit found for 5h. We modeled both (R,S)-10g and (S,S)-10g in this way (Figure S1). The (R,S)-10g and (S,S)-10g models gave distinct calculated ECD spectra, and comparison with the experimental spectra gave the best match for 10g-A = (R,S)-10g and 10g-B= (S,S)-10g, with a mean similarity score of 78.6% (Figure S2). This assignment is made with high confidence given that the mean similarity score for the opposite assignment is only 37.1%. To simplify the modeling further for future applications, we also modeled a phenylvinyl sulfoximine substructure of 10g that lacks the chiral amine functionality. We found that comparing the predicted ECD spectrum of substructure-10g with the experimental racemic-subtracted ECD spectrum of 10g gave the same assignment as modeling the full structure with a similar confidence level (δ score = 80.6%) (Figure S3).

pubs.acs.org/joc

Vinyl sulfonimidamide 19g was separated into its two enantiomers 19g-A and 19g-B, which were isolated in very high enantiomeric purity. The biaryl system is achiral and was anticipated not to make a significant contribution to the ECD spectrum, while the flexible nature of the alkyl linker would make the conformational modeling challenging. Accordingly, we modeled (R)-20 as the key substructure, which yielded three low-energy conformers. In analogy with vinyl sulfoximine 5h and 10g, the two lower-energy conformers (differing by 0.17 kcal mol⁻¹) have the vinyl group eclipsing the S=Obond, with the two structures varying in the orientation of the N-propargyl group, while for the higher-energy conformer $(+0.75 \text{ kcal mol}^{-1})$, the vinyl group eclipses the S=N bond (Figure S4). Comparing the calculated and experimental UVvis and ECD spectra led to an unambiguous assignment of **19g-A** = (R) and **19g-B** = (S) configurations with a high confidence (δ score = 91.5%) (Figure S5).

Chiral separation of 19f gave four stereoisomers 19f-A-D that were each isolated in high levels of stereo purity. By comparing the NMR spectra of each isomer, 19f-A and 19f-D were assigned as one enantiomeric pair and 19f-B and 19f-C as the other, although no information about their relative configuration could be obtained. We then modeled both (R,S)-19f and (S,S)-19f, which gave four and five low-energy $(\leq 1.5 \text{ kcal mol}^{-1})$ conformers, respectively, with the piperazine ring adopting a chairlike conformation and the phenyl ring pointing axially in each case (Figure S6). Conformers in which the phenyl ring points equatorially were substantially higher in energy (≥ 2.2 kcal mol⁻¹) for both (*R*,*S*)-19f and (*S*,*S*)-19f and made little-to-no contribution to the calculated ECD. Of note, while for (R,S)-19f the two lowest energy conformers have the vinyl group eclipsing S=O, for (S,S)-19f the lowest four conformers are of very similar energy, two them having the vinyl group eclipsing S=N, and two having it eclipse S=O. Determining the configuration of diastereoisomers by ECD is typically challenging because they often have closely related ECD spectral profiles. However, in this case, the calculated Boltzmann-weighted ECD spectra of all four stereoisomers gave strikingly different shapes. Comparing the UV and ECD spectra of each isomer with the modeled spectra, we found that 19f-A has a nearly exact match (98.9%) with (R,S)-19f and 19f-B gave an excellent match (97.4%) with (S,S)-19f, allowing us to make a high confidence assignment of all four isomers (Figure S7).

CONCLUSIONS

Vinyl sulfoximines and sulfonimidamides offer significant potential as functionalizable electrophilic warheads but have seen little exploration to date. We have developed several new synthetic approaches to these motifs that expand the potential of these motifs and access a much wider range of derivatives. First, we showcased a modified HWE sequence, from methyl sulfides, providing NH vinyl sulfoximines exclusively as the *E*isomers. Application of this HWE sequence to enantioenriched methyl sulfoximes. Next, we developed a two-step route to vinyl sulfoximines that exploits alkyne hydrothiolation and a highly chemoselective one-pot transfer of NH and O to vinyl sulfides. This route is substantially shorter than previous approaches and works well for both alkyl and aryl vinyl sulfoximines.

Terminal vinyl sulfoximine and sulfonimidamides represent particularly challenging synthetic targets that could have

Table 2. Chiral Separation and Configurational Assignment of Vinyl Sulfoximine and Sulfonimidamides Stereoisomers by Molecular Modeling and ECD

widespread application as warheads in covalent probes. We developed a simple two-step route to terminal vinyl sulfoximines from β -hydroxyethyl thioethers involving sulfoximine formation and alcohol activation/elimination. This approach is also extended to terminal vinyl sulfonimidamides, about which very little is known. Both vinyl sulfoximines and sulfonimidamides can be readily *N*-functionalized with an alkyne tag. These products have the potential to be utilized as fully functionalized probes in a range of chemical biology applications.

Finally, we developed a computational workflow for assigning the configuration of vinyl sulfoximines and sulfonimidamides using ECD. After validating the approach against a vinyl sulfoxide with a synthetically defined and known configuration, we apply the approach to the de novo assignment of enantiomeric and diastereoisomeric vinyl sulfoximines and vinyl sulfonimidamides. This methodology enables the implementation of chiral separation techniques to be applied to separate racemic vinyl sulfoximines and sulfonimidamides and assign their configuration, giving access to a range of new enantioenriched products.

Taken together, the methods we have exemplified in this work provide the tools to access new areas of electrophilic chemical space. Our investigations into the application of vinyl sulfoximines and sulfonimidamides to chemical biology are currently underway.

EXPERIMENTAL SECTION

General Experimental Considerations. All nonaqueous reactions were carried out under an inert atmosphere (argon) with flamedried glassware, using standard techniques. Anhydrous solvents were obtained by filtration through drying columns (tetrahydrofuran (THF), CH₂Cl₂, toluene). Forward-phase flash column chromatography was performed on an Isolera Spektra flash purification system using Biotage SNAP KP-Sil flash purification cartridges or SNAP Ultra flash purification cartridges, with the indicated solvent gradient. Reversed-phase flash column chromatography was performed using Biotage SNAP Ultra C18 cartridges. Analytical thin-layer chromatography (TLC) was performed on precoated aluminum-backed silica gel plates. Visualization of the developed chromatogram was performed by UV absorbance (254 nm) and/or stained with aqueous potassium permanganate solution, aqueous ceric ammonium molybdate, or a ninhydrin solution in ethanol. Nuclear magnetic resonance spectra were recorded on a 400 MHz spectrometer. Chemical shifts for ¹H NMR spectra are recorded in parts per million (ppm) from tetramethylsilane with the residual protic solvent resonance as the internal standard (chloroform: δ 7.27 ppm, methanol: δ 3.31 ppm). Data are reported as follows: chemical shift (multiplicity [s, singlet; d, doublet; t, triplet; m, multiple; and br, broad], coupling constant (in hertz), integration). ¹³C NMR spectra are recorded with complete proton decoupling. Chemical shifts are reported in parts per million from tetramethylsilane with the solvent resonance as the internal standard (¹³CDCl₃: δ 77.0 ppm, ¹³CD₃OD: δ 49.0 ppm). ¹⁹F NMR spectra were recorded with complete proton decoupling. Chemical shifts are reported in parts per million, referenced to fluorobenzene as a standard at δ –113.5 ppm. Commercial reagents were used as supplied or purified by standard techniques where necessary. Optical rotations (α') were recorded at the indicated temperature ($T \circ C$) and were converted to the corresponding specific rotations $[\alpha]_{D}^{T}$

Computational Methods. All calculations were performed using Gaussian 16.⁶³ Stationary points were confirmed using frequency calculations (default divergence criteria). Conformational searches were carried out as described in the Supporting Information. Electronic circular dichroism spectra were calculated for individual conformers using time-dependent density-functional theory (TDDFT) calculations at cam-B3LYP/6-311++g(d,p) in a continuum solvent (CPCM) acetonitrile for up to 200 states. Copies of Gaussian log files for optimizations and frequency calculations, TDDFT calculations, and tables of ECD data are available from a data depository via the data-set collection DOIs 10.14469/hpc/7859 (sulfoximines) and 10.14469/hpc/7577 (sulfonimidamides) and data sets cited therein.

Electronic Circular Dichroism. The circular dichroism and UV– vis spectra were recorded on a Chirascan spectrometer (Applied Photophysics). A 0.1 cm path-length cuvette was loaded with 200 μ L of each compound (50 μ M in acetonitrile) or acetonitrile blank. The elipticity was measured from 340 to 195 nm in 1.0 nm intervals (bandwidth = 2.0 nm) for 1.0 s per measurement. Measurements were taken in duplicate and normalized against the acetonitrile control.

Configurational Assignment by Comparison of the Calculated and Experimental ECD. Comparative analysis was performed using SpecDis.⁵² For each structure/substructure, the computed ECD and UV-vis spectra were summed according to their Boltzmann weighting at 298 K. The relevant experimental ECD and UV-vis spectra were then input and similarity analysis was performed by first aligning the UV spectra (shift range = -30 to +30 nm; bandwidth = 0.1-0.3; energy range = 200-340 nm) and then performing a local refinement to optimize the alignment of the ECD. Assignments were made on the basis of both manual inspection of the ECD alignments and the quantification of the similarity scores.
