Keywords: Synthesis Uronic acid Glucuronic acid Iduronic acid Glucosamine Heparin Heparan sulfate

#### 1. Introduction

Heparin (HP) and heparan sulfate (HS) are highly sulfated polysaccharides, and are the most complex carbohydrates among the glycosaminoglycan (GAG) superfamily.<sup>1</sup> HP/HS are basically composed of a repeating  $\alpha$  or  $\beta(1,4)$ -linked disaccharide unit, which is derived from uronic acid, either glucuronic acid or iduronic acid, and N-acetyl-glucosamine residues. The structure is very heterogeneous and contains various substitution patterns derived from the multiple and random enzymatic modifications in their biosynthesis. The diverse micro- or domain structure, which is derived from the enzymatic modification, is considered to regulate the activity of many important biological proteins, such as growth factors, cytokines, viral proteins, and coagulation factors, through their binding interactions in many biological processes.<sup>1,2</sup> The elucidation of the structure-function relations of HP/HS microstructures at the molecular level is, however, very difficult due to their naturally occurring structural diversity. Therefore, structurally defined HP/HS sequences (oligosaccharides) are essential for the precise understanding of the interactions of HP/HS with their

#### ABSTRACT

The monosaccharide moieties found in heparin (HP) and heparan sulfate (HS), glucosamine and two kinds of uronic acids, glucuronic and iduronic acids, were efficiently synthesized by use of glucosamine hydrochloride and glucurono-6,3-lactone as starting compounds. In the synthesis of the disaccharide building block, the key issues of preparation of uronic acids (glucuronic acid and iduronic acid moieties) were achieved in 12 steps and 15 steps, respectively, without cumbersome C-6 oxidation. The resulting monosaccharide moieties were utilized to the syntheses of HP/HS disaccharide building blocks possessing glucosamine–glucuronic acid (GlcN–GlcA) or iduronic acid (GlcN–IdoA) sequences. The disaccharide building blocks were also suitable for further modification such as glycosylation, selective deprotection, and sulfation.

target molecules. Many synthetic approaches to the synthesis of HP/HS oligosaccharides have been so far performed.  $^{\rm 3-7}$ 

Recently, a synthetic strategy for the assembly of a HP/HS oligosaccharide library has attracted much attention, because it offers a more comprehensive evaluation of HP/HS biological functions.<sup>4c,5,6a</sup> For this accomplishment, the efficient synthesis of uronic acid moieties and disaccharide building blocks accessible to HP/HS oligosaccharides with various sugar and sulfation patterns is required. As neither idose nor iduronic acid derivatives are commercially available, their syntheses are especially important. Currently, iduronic acid moieties are synthesized from glucose or glucuronic acid as a starting material, involving C-5 epimerization and/or C-6 oxidation.<sup>7</sup> But C-5 epimerization sometimes needs to be carried out under harsh conditions, such as, strong basic conditions, and the range of usable protective groups is restricted. C-6 Oxidation is also sometimes problematic in yield and repeatability. So far, many intermediates suitable for the structure of HP/HS have been developed as HP/HS building blocks.<sup>3-7</sup>

Previously, we reported the synthesis and analysis of a variety of HP/HS oligosaccharides for investigating their binding properties,<sup>6</sup> in which we clarified that an appropriate HP/HS disaccharide structure was needed for the specific binding between sugar component and protein. Although further investigation of HP/HS binding properties was needed, our previous synthetic route was

not suitable for the generation of a sufficiently diverse sugar and sulfation pattern. In this study, we synthesized novel disaccharide building blocks for the systematic analysis of HP/HS binding properties.

#### 2. Results and discussion

Our synthetic strategy is shown in Figure 1. The two disaccharide building blocks containing *gluco*- and *ido*-type are prepared from two common monosaccharides, p-glucosamine and p-glucurono-6,3-lactone. They contain a diverse set of protective groups for generating various sulfation patterns. *O*-Sulfation is achieved by selective removal of benzoyl (Bz), 4-methoxybenzyl (MPM), and/or *tert*-butyldiphenylsilyl (TBDPS) groups. Conversion of the azido group to amine, *N*-sulfate, and/or *N*-acetate is achieved by reduction of azido group followed by *N*-sulfation and/or *N*-acetylation. A glucosamine moiety containing different protective groups is easily prepared from glucosamine. A levulinyl (Lev) group at 4-position is

introduced for the further elongation of the sugar chain. Two uronic acid moieties are prepared from glucurono-6,3-lactone, which is already oxidized at the *C*-6 position. The synthetic route is expected to be simple because a cumbersome oxidation step can be omitted. Conversion to *ido*-form is achieved by the inversion reaction at *C*-5 position on furanose form.

Syntheses of uronic acid moieties were carried out as shown in Scheme 1. Firstly, inexpensive glucurono-6,3-lactone **1** was transformed to 1,2-isopropylidene **2** according to the method reported previously.<sup>7m</sup> Obtained **2** was then converted to furanose **3** in 43% overall yield in four steps through simple protection and deprotection processes of hydroxy groups. The removal of the isopropylidene group on furanose **3** by treatment with trifluoroacetic acid (TFA) gave triol **4**. Conversion to pyranose form by 1,2-selective protection was then examined. First, 1,2-cyclic acetal protection to obtain pyranose form was used.<sup>4h,7a</sup> Unfortunately, the resulting uronic acid derivatives were a mixture of pyranose and furanose forms under the conditions of acetal formation, suggesting a lower

vield of the desired pyranose form under the thermodynamic control. Thus, 1,1,3,3-tetraisopropyldisiloxanylidene (TIPDS) as a 1,2-selective protection group was chosen to yield the kinetically controlled product. 1,2-Selective cyclic reaction with 1,3-dichloro-1,1,3,3-tetraisopropyldisiloxane (TIPDSCl<sub>2</sub>) was performed under the standard conditions<sup>8</sup> using imidazole as a base in DMF to afford pyranose form **5** in 85% yield with high pyranose-selectivity<sup>9</sup>  $(\alpha/\beta=5:3)$ . Levulinvlation of pyranose **5** gave 4-O-Lev **6**, which was subsequently treated with tetra-n-butylammonium fluoride (TBAF). The resultant was subjected to silvlation with a TBDMS group at the 1-position, benzoylation at the 2-position, and delevulinylation to afford the glucuronic acid moiety 8 as a glycosyl acceptor. Meanwhile, ido-furanose 10 was prepared by a general  $S_N^2$  reaction of the triflate of furanose **3** with LevONa. After removal of the Lev group, the iduronic acid moiety 10 was treated with TFA to afford triol 11. The reaction of triol 11 with TIDPSCl<sub>2</sub> and imidazole efficiently proceeded when  $CH_3CN$  was used as a solvent at -45 °C, providing the pyranose form **12** in 78% with  $\beta$ -selectivity. After levulinylation of 12 with LevOH, DCC, and TEA, iduronate 16 was then synthesized as a similar transformation to the synthesis of the glucuronic acid moietv 8.

Synthesis of the glucosamine donor **23** and **24** was carried out as shown in Scheme 2. Azido glucose **18**, which was prepared according to the method reported previously,<sup>10</sup> was converted to thioglycoside **19**. After removal of the acetyl group of thioglycoside **19**, hydroxyl groups at 4- and 6-positions were selectively protected with isopropylidene group. The remaining hydroxyl group was then protected with MPM group. The resultant was treated with AcOH to produce diol **21**. Selectively silylation of diol **21** at 6-position with TBDPS group followed by levulinylation at 4-position

gave thioglycoside donor **23**. Imidate donor **24** was also prepared in the usual manner.

Two kinds of disaccharide building blocks were then synthesized from the prepared monosaccharide moieties (Scheme 3). Glycosylation of the thioglycoside donor **23** and glucuronate **8** was carried out by use of *N*-iodosuccinimide (NIS) in the presence of TBDMSOTf<sup>11</sup> to give disaccharide **25** only in 31% yield but with high  $\alpha$ -selectivity. Thioglycoside **23** was ineffective on the glycosylation with iduronate **16**. In contrast, glycosyl imidate **24** was found to be an efficient donor in glycosylation both with glucuronate **8** and iduronate **16**. These reactions proceeded smoothly to produce disaccharide **25** and **26** in 83% and 77% yields with high  $\alpha$ -selectivity, respectively.

Next, we examined whether the disaccharide building blocks could apply to further modifications like sugar-chain elongation, selective deprotection, sulfation, and final deprotection, or not. One of our goals is the assembly of an HP/HS disaccharide partial structure library, in order to determine the structure–function relations of their interactions with HP/HS binding molecules using Sugar Chips. In our Sugar Chips system, a glucose moiety spacer is often used at the reducing terminal. To prepare the oligosaccharides for use in this system, we carried out syntheses of trisaccharides containing GlcN–UroA–Glc (Scheme 4) and GlcN–IdoA–Glc sequence (Scheme 5). The disaccharide building block **25** was first converted to glycosyl donor **28** via selective desilylation at 1-position followed by formation of imidate. Glycosylation of spacer **29** with obtained **28** proceeded smoothly to give trisaccharide **30** in satisfactory yield.

Meanwhile, the disaccharide building block **26** was selectively converted to 1-OH form **31** by treatment of HF pyridine, although there was no selectivity by treatment of TBAF. Trisaccharide **33** was prepared in a manner similar to that of trisaccharide **30**.

Selective sulfation and final deprotection were examined on trisaccharide **30**. The Lev group of trisaccharide **30** was selectively deprotected by hydrazine. The occurring hydroxyl group was masked with a methyl group as in our previous study.<sup>6a</sup> After removal of the TBDPS group in compound **34**, the Bz group and methyl ester were hydrolyzed with NaOH. The azide group was then reduced with PMe<sub>3</sub> and the resulting amino group was *N*-sulfated. Finally, all benzylic protective groups were removed by hydrogenolysis using catalytic Pd/ C to give the desired trisaccharide **38** (Scheme 6).

In conclusion, we have designed novel disaccharide building blocks for HP/HS oligosaccharide precursors, which possess orthogonally cleavable protective groups and are capable of generating diverse sulfation patterns. Two disaccharide building blocks were efficiently synthesized using appropriate monosaccharide moieties. Syntheses of uronic acid moieties, which are key issues in the synthesis of HP/HS oligosaccharide, were efficiently prepared using inexpensive glucurono-6,3-lactone as a starting compound avoiding annoying oxidation processes. Selective pyranose formation was achieved using TIDPS group as protecting group at 1,2position. Glucuronate **8** and iduronate **16** were synthesized in 14% (12 steps) and 5% (15 steps) overall yield from glucurono-6,3lactone, respectively. In addition, we demonstrated the synthesis of sulfated trisaccharide **38**, which was achieved by selective deprotection and sulfation. Although further work will be needed to achieve such goals as sugar-chain elongation, sulfation at other positions, and deprotection, is required, various HP/HS oligosaccharides can be prepared by use of these designed disaccharide building blocks with minimal derivatization.

<sup>1</sup>H and <sup>13</sup>C NMR spectra were measured with a JEOL JMM-ECA600KS spectrometer. The chemical shifts in CDCl<sub>3</sub> are given in  $\delta$  values from tetramethylsilane as an internal standard. For measurement in D<sub>2</sub>O, the DHO signal (4.65 ppm) was used as a reference. Mass spectra were obtained on a micrOTOF II<sup>TM</sup> (Bruker Daltonics). Silica gel column chromatography was carried out using silica gel 60B (Fuji Silysia, 40–63 µm) at medium pressure (2–4 kg/cm<sup>2</sup>). Precoated Kieselgel 60 F<sub>254</sub> (Merck) was used for thin layer chromatography (TLC). Sephadex G25 fine was used for gel filtration chromatography. All chemicals were commercial grade (Nacalai, Wako, TCI, Kanto, and Aldrich). MS4A powder was activated by heating at 350 °C in vacuo for 3 h before use.

#### 3.2. 1,2-O-Isopropylidene-α-D-glucurono-6,3-lactone (2)

D-Glucurono-6,3-lactone **1** (40.0 g, 0.227 mol) was suspended in acetone (835 ml). H<sub>2</sub>SO<sub>4</sub> (12.1 ml, 0.227 mol) was then added at room temperature. After being stirred for 38 h, the reaction mixture was neutralized with NaHCO<sub>3</sub>. After removal of insoluble materials by filtration, the filtrate was concentrated in vacuo. The residue was dissolved in AcOEt, and the resulting mixture was then washed with brine, dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and concentrated in vacuo. Crystallization from AcOEt and hexane afforded isopropylidene **2** as a white solid. Yield 41.2 g (84%). <sup>1</sup>H NMR (600 MHz, CDCl<sub>3</sub>) δ 6.00 (1H, d,  $J_{1,2}$ =3.4 Hz, H-1), 4.96 (1H, dd,  $J_{4,3}$ =2.7 Hz,  $J_{4,5}$ =4.8 Hz, H-4), 4.84–4.83 (2H, m, H-2, H-3), 4.51 (1H, d,  $J_{5,4}$ =4.8 Hz, H-5), 2.86 (1H, s, 5-OH), 1.53 (3H, s, CH<sub>3</sub>), 1.36 (3H, s, CH<sub>3</sub>); <sup>13</sup>C NMR (150 MHz, CDCl<sub>3</sub>) δ 174.7, 113.6, 106.6, 82.9, 81.2, 77.9, 70.6, 26.9, 26.5; HRMS (positive mode) found: m/z 239.0536 [M+Na]<sup>+</sup>, calcd for C<sub>9</sub>H<sub>12</sub>O<sub>6</sub>Na: 239.0532.

### 3.3. Methyl 3-O-benzyl-1,2-O-isopropylidene- $\alpha$ -D-glucofuranosyluronate (3)

To a solution of compound 2 (56.9 g, 0.263 mol) in  $CH_2Cl_2$ (400 ml) were added imidazole (35.8 g, 0.526 mol) and TBDMSCl (47.6 g, 0.316 mol) at room temperature. After being stirred for 7.5 h, the reaction was quenched with MeOH. The resulting mixture was washed with 1 M HCl aq, satd NaHCO<sub>3</sub> aq, and brine. The organic layer was dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and concentrated in vacuo. The residue was then dissolved in MeOH (500 ml) and 1 M NaOMe in MeOH (39.4 ml, 39 4 mmol) was added at 0 °C. After being stirred for 3.5 h, the reaction mixture was neutralized with 1 M HCl ag and AcOEt was added. The organic layer was washed with 1 M HCl aq  $(2\times)$ , water and brine, dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and concentrated in vacuo to give crude methyl 4-O-tert-butyldimethylsilyl-1,2-O-isopropylidene-α-D-glucofuranosyluronate. The crude product, benzylimidate (132 ml, 0.526 mol), and MS4A powder (50 g) were placed in 1000 ml round-bottom flask, and anhydrous CH<sub>2</sub>Cl<sub>2</sub> (500 ml) was added at room temperature under Ar. After being stirred for 1 h, the reaction mixture was cooled to -30 °C and TBDMSOTf (7.86 ml, 34.2 mmol) was added at the same temperature. The reaction mixture was further stirred and gradually warmed to 0 °C. After 15 h, the reaction was quenched by the addition of EtOH. The resulting mixture was filtered through a Celite pad and the filtrate was concentrated in vacuo. The residue was dissolved in CH<sub>2</sub>Cl<sub>2</sub> and the mixture was washed with water and brine. The organic layer was dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and concentrated in vacuo to give crude methyl 3-O-benzyl-4-O-tertbutyldimethylsilyl-1,2-O-isopropylidene-α-D-glucofuranosyluronate. The crude product was then dissolved in THF (300 ml) and AcOH (15 ml). The mixture was cooled to -20 °C and 1 M TBAF in THF (789 ml, 0.789 mol) was added to the mixture at the same temperature. After being stirred for 3 h, the mixture was concentrated in vacuo and diluted in AcOEt. The organic layer was washed with brine (3×), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and concentrated in vacuo. Flash chromatography (silica gel: 450 g, hexane/AcOEt=6:1→2:1) afforded compound **3** as a brown oil.
