# Synthesis of 3,5-Disubstituted Isoxazoles through a 1,3-Dipolar Cycloaddition Reaction between Alkynes and Nitrile Oxides Generated from O-Silylated Hydroxamic Acids

Laure-Elie Carloni,<sup>[a]</sup> Stefan Mohnani,<sup>[a]</sup> and Davide Bonifazi\*<sup>[b]</sup>

**Abstract:** In this paper, we report the regioselective synthesis of 3,5-disubstituted isoxazoles by 1,3-dipolar cycloaddition between alkynyl dipolarophiles and nitrile oxide dipoles generated in-situ from *O*-silylated hydroxamic acids in the presence of trifluoromethanesulfonic anhydride and NEt<sub>3</sub>. Thanks to the mild, metal-free and oxidant-free conditions that this strategy offers, the reaction was successfully applied to a wide variety

### Introduction

Identified in countless biologically active derivatives, such as chlorophyll, amino acids, nucleobases and vitamins, five- and six-membered heterocycles are of greatest importance to life, drug discovery and medicinal chemistry.<sup>[1]</sup> Among them, isoxazoles form a major class of five-membered heterocycles with two heteroatoms (Figure 1).<sup>[2]</sup> Isoxazoles are key pharmacophores occurring in many natural products, e.g. ibotenic acid 1 and muscimol 2,<sup>[3]</sup> in a variety of bioactive compounds, such as anti-inflammatories 3 and 4,<sup>[4]</sup> monoamine oxidase inhibitor 5,<sup>[5]</sup> penicillin antibiotic 6,<sup>[6]</sup> and herbicidal isoxaflutole 7.<sup>[7]</sup> Isoxazoles have other biological properties as antitubulin, antinociceptive and anticancer.<sup>[8]</sup> They also find applications in material science, e.g. molecular switches and polymer syntheses.<sup>[9]</sup> Furthermore, these heterocycles constitute an important organic synthetic tool. Indeed, although isoxazoles are hydrolytically stable, they can be cleaved under reducing or basic conditions, leading to different important latent functionalities, namely 1,3-dicarbonyl compounds **8**, enaminones **9**, and  $\beta$ amino carbonyls 10 (Figure 1).<sup>[2,10]</sup> As a result, many research groups have used isoxazole derivatives as masked functions in synthetic strategies towards heterocyclic compounds and natural products.<sup>[11]</sup> Isoxazoles, and their partially saturated analogues, can be prepared using diverse synthetic strategies.<sup>[12]</sup> Among them, the 1,3-dipolar cycloaddition reaction between nitrile oxides and corresponding alkenyl and alkynyl dipolarophiles is probably the most convenient, attractive and direct

of alkynyl dipolarophiles, demonstrating the tolerance of this approach to diverse functional groups. In particular, we have shown that the method was compatible with biological molecules such as peptides and peptide nucleic acids (PNA). This protocol constitutes another example of metal-free 1,3-dipolar cycloaddition leading to the regioselective formation of isoxazoles.

approach, via a preferred in-situ preparation of the dipoles.<sup>[1b,2,12a,13]</sup> Indeed, as *Quilico* demonstrated in 1970, nitrile oxides in the presence of none or poor trapping agents, readily dimerize to furoxans.<sup>[14]</sup> They can also dimerize to 1,2,4-oxadiazole 4-oxide in the presence of NEt<sub>3</sub>.<sup>[13a,13b,15]</sup>

Several methods towards the in-situ generation of nitrile oxides have thus been developed, two of which are by far the most popular and well-established protocols. The first approach, namely the *Mukaiyama* method (Figure 2, *Method a*), involves the dehydration of nitroalkanes by aryl isocyanates in the presence of NEt<sub>3</sub>.<sup>[13c]</sup> The use of POCl<sub>3</sub>, MeSO<sub>2</sub>Cl and BzCl as dehydrating agents are improved variants of the original Mukaiyama procedure.<sup>[13a,13b,13d,16]</sup> The action of DMAP and Boc<sub>2</sub>O<sup>[17]</sup> or DMTMM<sup>[18]</sup> on nitroalkanes was also successfully used to give nitrile oxide dipoles. The second method relies on the base-mediated dehydrochlorination of hydroximoyl chlorides to yield the desired nitrile oxides (Figure 2, Method b).<sup>[13]</sup> This procedure is often carried out as a halogenation/dehydrohalogenation reaction on the parent aldoximes, especially for unstable hydroximoyl chlorides.<sup>[13a,13b]</sup> NCS, tBuOCl or NaOCl in the presence of NEt<sub>3</sub>, or chloramine-T without additional bases, are frequently employed in these procedures.<sup>[13e,13f]</sup> On top of these approaches, the direct oxidation of aldoximes through the use of MnO<sub>2</sub><sup>[19]</sup> or organic hypervalent iodine reagents<sup>[20]</sup> is also a promising route to the in-situ generation of nitrile oxides (Figure 2, Method c). Another strategy was described by Carreira and co-workers in 2000.<sup>[21]</sup> It involves the treatment of O-silylated hydroxamic acids with Tf<sub>2</sub>O in the presence of NEt<sub>3</sub> (Figure 2, Method d). In 2019, Dai et al. reported a novel direct Csp<sup>3</sup>-H bond functionalization of 2-methyl ketones and 2-methylquinoline with tBuONO, generating nitrile oxide in-situ via a radical mechanism (Figure 2, Method e).<sup>[22]</sup>

Although the cycloaddition between nitrile oxides and alkenyl derivatives is well-developed, the reaction with alkynyl dipolarophiles is usually affected by side reactions, often leading

Figure 1. Examples of natural products (1–2) and bioactive compounds (3–7) bearing an isoxazole function. Isoxazoles can also be used as masked functional groups for various synthetic strategies e.g. towards 8–10.

Figure 2. Overview of the synthetic approaches for preparing nitrile oxides in-situ: a) dehydration of nitroalkanes; b) dehydrochlorination of hydroximoyl chlorides; c) oxidation of aldoximes; d) oxidation of *O*-silylated hydroxamic acids; and e) Csp<sup>3</sup>-H bond functionalization of 2-methylketones with *t*BuONO.

to by-products and low yields. This is due to the relatively inert character of the triple bond. Following the Cu(I)-catalyzed azide-alkyne cycloaddition protocol,<sup>[23]</sup> it was also demonstrated that the addition of Cu(I)-<sup>[24]</sup> or Ru(II)-based<sup>[25]</sup> catalysts to a mixture of alkynes and nitrile oxides, the latter species being generated in-situ respectively from the parent aldoximes and hydroximoyl chloride, led to the formation of 3,5-di or 3,4-di and 3,4,5-trisubstituted isoxazoles in high yields. Among the metal-free protocols, the group of Heaney conjugated aryl moieties with DNA on solid phase through a 1,3-dipolar cycloaddition between nitrile oxide and alkynyl moieties.<sup>[26]</sup> In their approach, nitrile oxide was generated in-situ by dehydrogenation of aryl aldoxime. In 2011, the group of Van Delft described an efficient phenyliodine bis(trifluoroacetate) (PIFA)-mediated synthesis of isoxazoles.<sup>[20b]</sup> In a parallel avenue, Kankala et al. reported in 2011 the nucleophilic organocarbene-catalyzed 1,3dipolar cycloaddition of nitrile oxides with alkynes.<sup>[27]</sup> In 2014, the group of Pal reported the use of polyethylene glycol to facilitate the 1,3-dipolar cycloaddition of benzoylnitromethane

and ethyl 2-nitroacetate with terminal alkynes leading to isoxazoles under green conditions.<sup>[28]</sup> Recently, the Csp<sup>3</sup>-H metalfree radical functionalization/cycloaddition cascade from ketones, alkynes and *t*BuONO proposed by Dai et al. allowed the synthesis of 3-acyl and 3-quinoline isoxazoles in moderate to good yield.<sup>[22]</sup>

While studying metal-free methodologies for the bioconjugation of structures of biological interest with functional organic dyes,<sup>[29]</sup> our group became interested in developing an alternative bioconjugation approach that would use the 1,3dipolar cycloaddition reaction between a nitrile oxide and an alkynyl derivative to produce isoxazole linkers. During these endeavors, we focused our attention on the Carreira's protocol,<sup>[21]</sup> that produces isoxazolines via cycloaddition between an alkenyl derivative and a nitrile oxide, the latter being produced in-situ from O-silylated hydroxamic acids upon treatment with Tf<sub>2</sub>O and NEt<sub>3</sub> (Figure 2, Method d). In addition to the mild, metalfree and oxidant-free conditions that this strategy offers, we conjectured that the straightforward preparation of the parent O-silylated hydroxamic acids 11<sup>R1</sup> could also be easily adapted on a large variety of substrates. Indeed, O-silylated hydroxamic acids can be readily obtained from the corresponding hydroxamic acids 12<sup>R1</sup> by silvlation with tert-butyl(chloro)diphenylsilane in the presence of NaH (Scheme 1a). They can also be prepared from the corresponding carboxylic acids 13<sup>R1</sup> by reaction with O-silylated hydroxylamine 14[30] following activation of the carboxylic acid moiety with HATU in the presence of DIEA (Scheme 1b). To our surprise, this method has not been used to prepare isoxazoles. It is with this aim that herein we report the successful adaptation of the Carreira's protocol to the regioselective preparation of 3.5-disubstituted isoxazoles (Scheme 1c) through the 1,3-dipolar cycloaddition reaction between in-situ generated nitrile oxides (15<sup>R1</sup>) and alkynyl dipolarophiles 16<sup>R2</sup>.

Scheme 1. Synthetic protocol proposed in this work: formation of *O*-silylated hydroxamic acids  $11^{R1}$  a) from hydroxamic acid derivatives  $12^{R1}$ , and b) from parent acids  $13^{R1}$ . Yields were 72 % and 44 % for  $R^1 = Ph$ , respectively. c) Optimized 1,3-dipolar cycloaddition developed in this work for preparing 3,5-disubstituted isoxazoles  $17^{R1,R2}$ .

#### **Results and Discussion**

We commenced our studies with the investigation of the basic reactivity of alkynes respect to alkenes in the 1,3-dipolar cycloaddition reaction with *O*-silylated hydroxamic acid **11a** ( $R^1$  = Ph). This was achieved using aliphatic compounds 1-octyne **16a** and 1-octene **18**, following *Carreira*'s procedure (Scheme 2).<sup>[21]</sup> Hence, after dropwise addition of 1  $\bowtie$  Tf<sub>2</sub>O in CH<sub>2</sub>Cl<sub>2</sub> to a solution of **11a** and NEt<sub>3</sub> in CH<sub>2</sub>Cl<sub>2</sub> at -40 °C, the reaction mixture was allowed to stir for 1 h at 0 °C, after which an 8-fold excess of dipolarophile<sup>[31]</sup> **16a** or **18** was added, and the solution stirred overnight at r.t. Desired isoxazole **17a** and isoxazoline **19** were successfully synthesized in 49 % and 79 % isolated yield, respectively. The 30 % difference in yield between the two reactions confirmed the expected lower reactivity of alkynes.<sup>[32]</sup>

Scheme 2. Evaluation of the reactivity of 1-octyne **16a** respect to 1-octene **18** in the 1,3-dipolar cycloaddition reaction with nitrile oxide **15a**, generated in-situ from *O*-silylated hydroxamic acid **11a**.

Next, we attempted to improve the cycloaddition yield with 1-octyne **16a**.<sup>[33]</sup> First, all side-products were isolated and compared to those obtained in a second trial in which no dipolarophile had been added to the reaction mixture. We observed that these side-products (Scheme 3, **20/21**), of which structures **21** were proposed with the support of literature,<sup>[13a,15]</sup> were identical in the absence and in the presence of 1-octyne. This observation suggested that the side-reactions mainly derive

from nitrile oxide 15a and are independent on the dipolarophile. With this information in hand, we attempted the optimization of the reaction, with the idea of favoring the intermolecular cycloaddition reaction over the other side-reactions. Several conditions were explored, mainly focusing on the nitrile oxide generation.<sup>[33]</sup> Parameters such as the excess of the dipolarophile, time, temperature, the order of addition of the reagents, as well as the concentration of the reaction mixture were studied. Although none of these tests gave improved yields, we could conclude that: (i) the side-products mainly derived from the reaction of nitrile oxide 15a with itself or with 20a (Scheme 3); (ii) these side-reactions do not take place below 0 °C; and (iii) they are faster than the 1,3-dipolar cycloaddition with 1octyne at r.t. In light of these observations, we decided to monitor the generation of nitrile oxide at different temperatures, and noticed that it is formed within three minutes at -40 °C. This observation allowed us to improve the protocol. Namely, the reaction mixture was allowed to stir only for 3 min at -40 °C after the addition of Tf<sub>2</sub>O to a solution of **11a**, before it was cannulated over 1 h onto neat 1-octyne 16a at r.t. The solution was then stirred overnight at r.t. (Scheme 1c). Following this procedure, desired isoxazole 17a was formed in 75 % yield, with an overall increase of 26 %. To the best of our knowledge, this is one of the most efficient synthetic strategies to form 5-hexyl-3-phenylisoxazole 17a.<sup>[34]</sup> Similar yields were obtained either using the base-mediated conversion of propargylic N-hydroxylamines, through a detosylative 5-endo-dig-cyclisation,<sup>[34a]</sup> or exploiting hypervalent iodine to generate in-situ the nitrile oxide species.<sup>[34b]</sup> Having in our hands the optimal conditions for our transformation, we extended the protocol to a variety of Osilylated hydroxamic acids 11<sup>R1</sup> and of alkynyl substrates 16<sup>R2</sup> (Scheme 4).

Scheme 3. Reaction side-products **20** are formed during the formation of nitrile oxide. By-products **21** derive from the dimerization of nitrile oxides. Reported structures **21** are proposals which were assigned with the support of literature.<sup>[13a,15]</sup>

We started by studying the effect of electron-withdrawing groups (EWG) and electron-donating groups (EDG) on the alkynyl reagent.<sup>[32]</sup> Reactions were carried out between *O*-silylated hydroxamic acid **11a** and aromatic alkynes: ethynylbenzene **16b** as a reference, electron-poor 1-ethynyl-4-(trifluoromethyl) benzene **16c** and electron-rich 4-ethynyl-*N*,*N*-dimethylaniline **16d**. When adding the alkyne in one batch onto benzonitrile oxide (according to Scheme 2),<sup>[21]</sup> both activated dipolarophiles

Scheme 4. Scope of this work: the optimized protocol for the 1,3-dipolar cycloaddition reaction between alkynyl dipolarophile **16<sup>R2</sup>** and nitrile oxide **15<sup>R1</sup>** generated in-situ from *O*-silylated hydroxamic acid **11<sup>R1</sup>** was applied to a variety of substrates leading to diverse isoxazoles **17<sup>R1,R2</sup>**. Isolated yields are reported. [a] 65 % with original *Carreira*'s protocol. [b] Measured %area of desired cycloadduct in the RP-HPLC chromatogram of the crude reaction mixture. [c] Calculated from 49 % conversion, as determined from the RP-HPLC chromatogram of the crude reaction mixture.

**16c** and **16d** gave the corresponding desired isoxazoles in higher yield than reference ethynylbenzene **16b** (ca. 65 % isolated yield respect to 54 %).

The cycloaddition reaction yields were increased with ethynylbenzene **16b** and 1-ethynyl-4-(trifluoromethyl) benzene **16c** by cannulating the nitrile oxide into a solution of the dipolarophile (Scheme 1c). Indeed, both dipolarophiles afforded desired isoxazoles **17b** and **17c** in 78 % of yield. On the other hand, 4ethynyl-*N*,*N*-dimethylaniline **16d** seemed to have decomposed to some extent under these conditions, thus giving a yield of 57 %. Although the isolated yield for 3,5-diphenyl isoxazole **17b** is slightly inferior to the protocols using PIFA (90 %)<sup>[20b]</sup> or a mixture of KCl and oxone in H<sub>2</sub>O (87 %),<sup>[35]</sup> our method gave similar results as those obtained with Cu(I)-catalyzed synthesis

Scheme 5. Synthesis of ethynylrhodamine 16f and further 1,3-dipolar cycloaddition reaction with nitrile oxide 15a. Upon formation of desired isoxazole 17f, the ring-opening of the spirolactam form was observed in the presence of acid.

of isoxazoles (72 %),<sup>[24]</sup> as well as to other metal-based oxidative<sup>[19,20c,20d,34b]</sup> and dehydrating strategies.<sup>[17]</sup>

Using the optimized procedure, we then evaluated the compatibility of the reaction conditions with other functional groups. The protocol afforded 3-phenyl-5-(trimethylsilyl)isoxazole 17e in 69 % when starting from O-silylated hydroxamic acid precursor 11a and ethynyltrimethylsilane 16e. The reaction was also successfully applied to ethynylrhodamine 16f (Scheme 5).<sup>[36]</sup> The 1,3-dipolar cycloaddition reaction with nitrile oxide 15a led to the formation of desired isoxazole 17f in 66 %. Upon formation of desired cycloadduct 17f, the ring-opening of the spirolactam moiety was observed, as described in Scheme 5.<sup>[37]</sup> Considering its application as molecular sensor, the result obtained with rhodamine B 22 was particularly interesting as this strategy offers a new route of functionalization of the fluorophore.<sup>[38]</sup> Indeed, modification of the N-terminus of the spiroamide moiety of **16f** with a conveniently functionalized dipole precursor, could allow its conjugation to various receptors for the targets of interests.

The 1,3-dipolar cycloaddition reaction was tested using ethynyltrimethylsilane **16e** with polycyclic aromatic dipoles **11b** and **11c**, namely with an anthracenyl and a naphthyl core, respectively. The corresponding *O*-silylated hydroxamic acids were synthesized according to Scheme 1b. The desired isoxazoles **17g** and **17h** were respectively generated in 71 % and 67 % isolated yields. The 1,3-dipolar cycloaddition reaction was also performed between naphthyl precursor **11c** and ethynylbenzene **16b** as well as 4-ethynyl-*N*,*N*-dimethylaniline **16d**. Corresponding isoxazoles **17i** and **17j** were formed in 72 % and 61 % yield, respectively.

The reaction was also extended to di- and tri-topic substrates, starting with the simple di-substitution pattern consisting of a 1,4-benzene core. The corresponding *O*-silylated hydroxamic acid **11d** was synthesized according to Scheme 1b from terephthalic acid in 48 % isolated yield, corresponding to 69 % per functionality. The 1,3-dipolar cycloaddition reaction with ethynyltrimethylsilane **16e** provided desired **17k** in 50 % yield, corresponding to 71 % yield per hydroxamic acid group. Next, we focused on a tris-1,3,5-benzene substituted core pattern. *O*-silylated hydroxamic acid derivative **11e** was synthesized in four steps (Scheme 6). First, 4-methoxycarbonylphenylboronic acid **23** was prepared by esterification of 4-carboxyphenylboronic acid **24** with MeOH in SOCI<sub>2</sub>.<sup>[39]</sup> Reaction with 1,3,5-tribromobenzene **25** in the presence of a catalytic amount of  $[Pd(PPh_3)_4]$  and Na<sub>2</sub>CO<sub>3</sub> under microwave conditions,<sup>[40]</sup> gave desired tricarboxylic acid derivative **26** after saponification with aqueous NaOH of resulting tris-ester **27**.<sup>[41]</sup> Activation of triscarboxylic acid **26** with HATU in the presence of DIEA, followed by reaction with *O*-silylated hydroxylamine **14**, afforded desired nitrile oxide precursor **11e**. Finally, subsequent cycloaddition reaction with ethynyltrimethylsilane **16e** provided desired trisisoxazole **17l** in 39 % yield, i.e. 73 % yield per functionality.

Lastly, we have studied the cycloaddition reaction between *O*-silylated hydroxamic acid **11a** and 1,2-diphenylethyne **16g** and with 1,4-diethynylbenzene **16h**. 3,4,5-triphenylisoxazole **17m** was obtained in less than 15 % yield. This is in line with the limited reactivity of internal alkynes with nitrile oxides, as it is well established that isoxazoles would exclusively be obtained from electron-deficient internal acetylenic dipolarophiles.<sup>[2b,42]</sup> On the other hand, only one of the two alkynyl moiety of 1,4-diethynylbenzene **16h** was successfully converted to isoxazole, leading to derivative **17n** in 18 % yield. We explained this result by considering the constraint imposed by 1,4-diethynylbenzene **16h** to work with an excess of nitrile oxide, favoring decomposition of the latter into by-products over its reaction with alkynyl dipolarophile **16h** (Scheme 3).

The 1,3-dipolar cycloaddition reaction was finally used to functionalize peptide and peptide nucleic acid (PNA) species. Both were synthesized on a solid phase semi-automatic peptide synthesizer (Focus XC), using a classical 9-fluorenylmethyl carbamate (Fmoc) solid-phase procedure (Scheme SI1) on a Rink Amide MBHA resin, with the required amino acids (aa) or PNA monomers.<sup>[43]</sup> A peptide sequence (KFRVGVADVC) displaying potential function in antitumor therapies<sup>[44]</sup> was selected, and synthesized (Section 6 in the SI). Functionalization at the Nterminal position with an acetylenic moiety was subsequently achieved to allow the 1,3-dipolar cycloaddition with nitrile oxides generated from O-silylated hydroxamic acid 11a (Scheme 7). The ethynyl moiety was introduced in the sequence by coupling 5-hexynoic acid with the relevant peptide precursor 28d under the standard solid-phase synthesis conditions (Scheme 7a). The 1,3-dipolar cycloaddition reaction with nitrile oxide 15a was then performed on solid phase (Scheme 7b). To this end, a 10-fold excess of nitrile oxide, generated in-situ from O-silylated

Scheme 6. Synthesis of tris-O-silylated hydroxamic acid precursor 11e and subsequent 1,3-dipolar cycloaddition reaction with ethynyltrimethylsilane 16e.

Scheme 7. a) Synthesis of resin-bound ethynyl-functionalized peptide **16i**; b) 1,3-dipolar cycloaddition reaction on solid phase between **16i** and nitrile oxide **15a**. The yield was calculated based on RP-HPLC chromatogram (%area) of the crude reaction mixture and on the measured 49 % conversion. PS = polystyrene;  $R^1$  = amino acid side chain. Sequence: KFRVGVADVC.

hydroxamic acid 11a with Tf<sub>2</sub>O in the presence of NEt<sub>3</sub> at -40 °C, was cannulated at the same temperature onto a suspension of resin-bound ethynyl-functionalized peptide 16i in DMF. The resulting mixture was heated at 50 °C and shaken for 16 h. This was followed by cleavage from the resin, complete deprotection of the side chains using an acidic cleavage mixture TFA/ H<sub>2</sub>O/EDT/TIPS, 94:2.5:2.5:1, precipitation with Et<sub>2</sub>O, and analysis of the resulting white solids by reverse phase HPLC (RP-HPLC). The RP-HPLC analysis of crude 170 displayed two major products, namely isoxazole 170, and cleaved starting material ethynyl-peptide 16i. Incomplete conversion was observed likely due to the favored side-reactions of nitrile oxide over the reaction with the alkynyl moieties when the former is in excess. Yet, the 1,3-dipolar cycloaddition reaction was shown to be compatible with peptidic structures and solid-phase synthesis. Based on the analytical RP-HPLC chromatogram of the crude reaction mixture, 49 % conversion of *N*-terminal ethynyl-peptide **16i** was obtained, of which 41 % corresponded to desired cyclo-added peptide 17o, and 8 % to unidentified side-products, thereby resulting in 84 % yield of peptide-isoxazole conjugate.

Next, the reaction was attempted on self-complementary PNA (sequence: (AATT)<sub>3</sub>-Lys), which was synthesized from the relevant Fmoc/benzyloxycarbonyl (Cbz)-protected PNA monomers. Solid phase synthesis, terminal functionalization with an acetylenic moiety and reaction with nitrile oxide **15a** following the same strategies as that described above for ethynyl-peptide **16i**, gave PNA-isoxazole conjugate **17p** formed in 43 % (yield calculated on the %area from the RP-HPLC chromatogram of the crude reaction mixture). No trace of ethynyl-functionalized PNA **16j** was detected.<sup>[33]</sup>

## Conclusions

In conclusion, we have successfully demonstrated the catalystand oxidant-free regioselective synthesis of 3,5-disubstituted isoxazoles by 1,3-dipolar cycloaddition reactions between alkynyl dipolarophiles and nitrile oxides, with the latter reagent being produced in-situ under mild conditions. The method is experimentally straightforward and convenient as it makes use of stable crystalline O-silylated hydroxamic acids dipole precursors readily synthesized from the corresponding hydroxamic or carboxylic acids. Through the application of the protocol to a variety of dipoles and dipolarophiles, we have observed that the mildness of this approach provides a tolerance to diverse functional groups as different 3,5-disubstituted isoxazoles were successfully synthesized in moderate to good yields. In particular, we have shown that the method was compatible with biological molecules such as peptides and PNA,<sup>[45]</sup> thus opening the way to the biorthogonal applications.<sup>[46]</sup> An isoxazole derivative of rhodamine B was also successfully formed, indicating that the strategy could provide a promising new functionalization route towards labelling and sensing applications.

## **Experimental Section**

**General Information:** Chemicals were purchased from Sigma Aldrich, Acros Organics, Fluorochem, TCI, aapptec, carbosynth, and ABCR, and were used as received from the commercial suppliers. Resins for solid-phase synthesis were purchased from Peptides International and aapptec. Solvents were purchased from Sigma Aldrich and Acros Organics. Deuterated solvents were purchased from Eurisotop. General solvents were distilled in vacuo. Anhydrous CH<sub>2</sub>Cl<sub>2</sub> was distilled from phosphorus pentoxide. Anhydrous DMF was purchased from Acros Organics. Low-temperature baths were prepared using different solvent mixtures depending on the desired temperature: -40 °C with CH<sub>3</sub>CN/liquid N<sub>2</sub>, -10 °C with ice/brine, and 0 °C with ice/H<sub>2</sub>O. Anhydrous conditions were achieved by drying Schlenk lines, 2-neck flasks or 3-neck flasks by flaming with a heat gun under vacuum and then purging with argon. The inert atmosphere was maintained using argon-filled balloons equipped with a syringe and needle that was used to penetrate the silicon stoppers used to close the flasks' necks. The addition of liquid reagents was done by means of dried plastic syringes or by cannulation, using standard inert atmosphere techniques. Microwave reactions were performed on a Biotage AB Initiator microwave instrument producing controlled irradiation at 2.45 GHz. Solid-phase peptide syntheses were performed on a semi-automatic FOCUS XC peptide synthesizer, coming with a computer/control system from aapptec. Reactions were monitored by thin-layer chromatography (TLC) using pre-coated aluminum sheets with 0.20 mm Machevery-Nagel Alugram SIL G/UV<sub>234</sub> with fluorescent indicator UV<sub>254</sub> or UV<sub>366</sub>. Components were visualized by illumination with shortwavelength UV light. All products were purified by flash column chromatography on Grace silica gel 60 (particle size 40-63 µm). Peptide and PNA oligomers were analyzed and purified by highperformance liquid chromatography (HPLC) on a Varian 940-LC liquid chromatograph system with a Varian Pursuit C18, 5 µm, 250  $\times$  4.6 mm analytical column and a Varian Pursuit C18, 5  $\mu$ m,  $250 \times 21.2$  mm preparative column. 0.1 % TFA in H<sub>2</sub>O and 0.1 % TFA in CH<sub>3</sub>CN were used as eluents in all cases. Lyophilisation was performed on a Christ Freeze Dryer ALPHA 2-4 LD<sub>plus</sub>, connected to a Vacuubrand Chemistry-HYBRID-pump, with an ice condenser temperature of approx. -85 °C and a vacuum of approx. 2.10<sup>-3</sup> mbar. <sup>1</sup>H and <sup>13</sup>C NMR spectra were obtained on a 400 MHz NMR (Jeol JNM EX-400). Chemical shifts were reported in ppm according to tetramethylsilane using the solvent residual signal as an internal reference (CDCl<sub>3</sub>:  $\delta_{H}$  = 7.26 ppm,  $\delta_{C}$  = 77.16 ppm; CD<sub>2</sub>Cl<sub>2</sub>:  $\delta_{H}$  = 5.32 ppm,  $\delta_{C}$  = 53.84 ppm; [D<sub>6</sub>]DMSO:  $\delta_{H}$  = 2.50 ppm,  $\delta_{C}$  = 39.52 ppm). Coupling constants (J) were given in Hz and were averaged. Resonance multiplicity was described as s (singlet), d (doublet), t (triplet), g (quartet), quin (quintet), m (multiplet), br (broad signal), dd (doublet of doublets). Carbon spectra were acquired with a complete decoupling for the proton.

General Experimental Procedure for the Preparation of O-(*tert*-Butyldiphenylsilyl)hydroxamic acids (11) – *Hydroxamic acid* route (Method A): A solution of benzhydroxamic acid (1 equiv.) in THF was treated at 0 °C with NaH (60 % in mineral oil, 2 equiv.) in two portions at 20 min intervals, under an inert atmosphere of argon. After 30 min, when all H<sub>2</sub> gas evolution had stopped, the solution was cooled to 0 °C, and *tert*-butylchlorodiphenylsilane (1.1 equiv.) was added dropwise over 30 min. The reaction mixture was then warmed up to r.t. and was stirred for additional 2 h. It was subsequently diluted with H<sub>2</sub>O and extracted with EtOAc. The organic extracts were washed with H<sub>2</sub>O and dried with anhydrous Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated to dryness in vacuo. The residue was purified by silica gel column chromatography to afford desired product **11**. With this procedure, we prepared derivative **11a**.

General Experimental Procedure for the Preparation of O-(*tert*-Butyldiphenylsilyl)hydroxamic acids (11) – *Carboxylic acid route* (*Method B*): To a suspension of benzoic acid (1 equiv.) in anhydrous

DMF were added DIEA (2 equiv.) and HATU (1.1 equiv.), in this order, under an inert atmosphere of argon. The resulting reaction mixture was stirred for 30 min at r.t., after which *O*-silylated hydroxylamine **14** (1.5 equiv.) was added at 0 °C and the resulting solution stirred overnight (approx. 16 h) at r.t. It was then concentrated to dryness in vacuo to yield a solid residue, which was dissolved in CH<sub>2</sub>Cl<sub>2</sub> and washed with H<sub>2</sub>O. The aqueous phase was extracted with CH<sub>2</sub>Cl<sub>2</sub> and the combined organic phases washed with H<sub>2</sub>O and brine, dried with anhydrous Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated to dryness in vacuo. The residue was purified by silica gel column chromatography to afford desired product **11**. With this procedure, we prepared derivatives **11a–e**.

**N-((tert-Butyldiphenylsilyl)oxy)benzamide (11a):** Synthesis according to Method A: Yield 72 % (492 mg) of desired product **11a** as a white solid. Synthesis according to Method B: Yield 44 % (2.69 g, white solid).  $R_{\rm f} = 0.42$  (Cyclohexane(Cy)/EtOAc, 95:5). m.p. 134-137 °C; <sup>1</sup>H NMR (400 MHz, [D<sub>6</sub>]DMSO, \*denotes rotamer peaks):  $\delta = 11.40 \& 10.92^*$  (s, 1H, NH), 7.76 (m, 4H, CH), 7.53–7.37 (m, 11H, CH), 1.11 (s, 9H, CH); <sup>13</sup>C NMR (100 MHz, [D<sub>6</sub>]DMSO):  $\delta = 166.5$ , 135.5, 132.7, 132.1, 131.4, 130.1, 128.4, 127.6, 127.2, 26.8, 19.2. All other spectroscopic and analytical properties were identical to those reported in the literature.<sup>[21]</sup>

*N*-((*tert*-Butyldiphenylsilyl)oxy)anthracenyl-9-carboxamide (11b), synthesis according to Method B: Yield 41 % (351 mg) of desired product **11b** as a yellow solid.  $R_f = 0.62$  (CH<sub>2</sub>Cl<sub>2</sub>/MeOH, 95:5). m.p. 91–94 °C; <sup>1</sup>H NMR (400 MHz, [D<sub>6</sub>]DMSO):  $\delta = 11.67$  (s, 1H, NH), 8.60 (s, 1H, CH), 8.04 (m, 2H, CH), 7.88 (m, 4H, CH), 7.57 (m, 2H, CH), 7.51–7.44 (m, 6H, CH), 7.30–7.23 (m, 4H, CH) 1.17 (s, 9H, CH), the proton assignment has been done by 2D analysis; <sup>13</sup>C NMR (100 MHz, [D<sub>6</sub>]DMSO):  $\delta = 165.7$ , 135.9, 131.4, 130.4, 130.3, 129.7, 128.2, 127.8, 127.7, 126.4, 125.5, 125.1, 26.9, 19.2 (one of the quaternary aromatic carbons overlaps with another signal); IR (cm<sup>-1</sup>):  $\tilde{v} =$ 507.3, 698.7, 709.2, 727.8, 737.9, 807.9, 888.5, 1060.0, 1116.1, 1427.5, 1471.0, 1498.4, 1648.9, 2856.9, 2929.8, 2955.5, 3052.6, 3200.4; MS (APCI-HR-MS): Found 476.2043 [M + H]<sup>+</sup>, C<sub>31</sub>H<sub>29</sub>NO<sub>2</sub>Si requires = 476.2046.

O-(tert-Butyldiphenylsilyl)hydroxylamine (14): To a stirred suspension of hydroxylamine hydrochloride (500 mg, 7.19 mmol) in anhydrous CH<sub>2</sub>Cl<sub>2</sub> (20 mL) was added NEt<sub>3</sub> (1.60 g, 2.21 mL, 15.83 mmol) under an inert atmosphere of argon. The mixture was allowed to stir for 1 h at r.t. Neat tert-butylchlorodiphenylsilane (2.18 g, 2.06 mL, 7.91 mmol) was added, and the reaction mixture allowed to stir overnight (approx. 16 h) at r.t. The mixture was then concentrated to dryness in vacuo and THF (10 mL) added to the crude. Triethylamine hydrochloride was removed as a white solid by filtration. The flask and precipitate were washed  $(3 \times 5 \text{ mL})$  with THF, and the resulting solution concentrated to dryness in vacuo. Ice-cold pentane (15 mL) was added to the residue, the mixture briefly sonicated and the compound allowed to crystallise in the fridge for 2 h. The solid was collected by filtration and washed with ice-cold pentane, yielding 14 (1.77 g, 91 %) as a white crystalline solid. m.p. 68–70 °C; <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  = 7.75–7.71 (m, 4H, CH), 7.44-7.39 (m, 6H, CH), 1.08 (s, 9H, CH), NH protons were not observed; <sup>13</sup>C NMR (100 MHz,  $CD_2CI_2$ ):  $\delta$  = 135.8, 134.1, 130.0, 128.0, 27.4, 19.4. All other spectroscopic and analytical properties were identical to those reported in the literature.<sup>[30]</sup>

3',6'-bis(Diethylamino)-2-(prop-2-yn-1-yl)spiro[isoindoline-1,9'xanthen]-3-one (16f): To a solution of rhodamine B 22 (1 g, 2.09 mmol) in anhydrous 1,2-dichloroethane (82 mL) was added dropwise POCl<sub>3</sub> (2.08 g, 1.26 mL, 13.58 mmol) with vigorous stirring, under an inert atmosphere of argon. The mixture was stirred under reflux at 80 °C for 6 h, after which it was cooled to r.t. and concentrated to dryness in vacuo. The resulting residue was dissolved in THF (30 mL) and treated with NEt<sub>3</sub> (1.21 g, 1.66 mL, 12.0 mmol), followed by propargylamine (121 mg, 0.14 mL, 2.2 mmol). The solution was stirred overnight (approx. 16 h) at r.t., after which it was concentrated to dryness in vacuo and subjected to silica gel column chromatography (eluent: CH<sub>2</sub>Cl<sub>2</sub>) yielding 68 % (685 mg) of desired product **16f** as a pale pink solid.  $R_f = 0.82$  (CH<sub>2</sub>Cl<sub>2</sub>). m.p. 191–193 °C; <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  = 7.93–7.90 (m, 1H, CH), 7.44–7.39 (m, 2H, CH), 7.10–7.08 (m, 1H, CH), 6.46 (d, J = 8.9 Hz, 2H, CH), 6.39 (d, J = 2.5 Hz, 2H, CH), 6.26 (dd,  $J_1 = 2.5$  Hz,  $J_2 = 8.9$  Hz, 2H, CH), 3.94 (d, J = 2.5 Hz, 2H, CH), 3.33 (q, J = 7.1 Hz, CH), 1.75 (t, J = 2.5 Hz, 1H, CH), 1.15 (t, J = 7.1 Hz, 12H, CH); <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>):  $\delta$  = 167.4, 153.8, 153.5, 148.8, 132.6, 130.4, 129.1, 128.0, 123.8, 122.9, 107.9, 105.1, 97.8, 78.3, 70.1, 64.8, 44.4, 28.5, 12.6. **VGVA Acetylenic Peptide (16i):** Acetylenic-peptide **16i** was synthesised on 200 mg scale, following the strategy described on Scheme SI1, using the appropriate amino acids. Following synthesis of the desired sequence, 5-hexynoic acid (68.9 mg, 68  $\mu$ L, 0.615 mmol) was used in place of an amino acid, and a double coupling was achieved in order to ensure a quantitative reaction. An aliquot of the resulting crude was isolated, cleaved from the resin and analyzed by RP-HPLC. The cleavage cocktail mixture used was TFA/H<sub>2</sub>O/EDT/TIPS, 94:2.5:2.5:1. The cleavage took place for 4 h, under an inert atmosphere of argon. Peptide **16i** was isolated as a white solid, soluble in a mixture of H<sub>2</sub>O/CH<sub>3</sub>CN, 1:1 + 0.1 % TFA. HPLC retention time: 29.4 min. MS (ESI-HRMS): Found 1186.6520 [M + H]<sup>+</sup>, 593.8314 [M+2H]<sup>2+</sup>, which resolved to 1185.6456 ± 0.0053 [M], C<sub>54</sub>H<sub>87</sub>N<sub>15</sub>O<sub>13</sub>S requires = 1185.6328. Additional synthetic and analytical details are described in the supporting information.

(AATT)<sub>3</sub> Lys Acetylenic PNA (16j): Acetylenic PNA dodecamer 16j was synthesised on 250 mg scale, following the strategy described on Scheme SI1, using the appropriate amino acid (lysine) and PNA monomers. Following synthesis of the desired sequence, 5-hexynoic acid (68.9 mg, 68  $\mu$ L, 0.615 mmol) was used in place of a PNA monomer, and a double coupling was achieved in order to ensure a quantitative reaction. An aliquot of the resulting crude was isolated, cleaved from the resin. The Cbz-protecting groups were deprotected. Resulting deprotected PNA 16j was isolated as a white solid, soluble in H<sub>2</sub>O. HPLC retention time: 11.4 min. MS (MALDI-MS): Found 3487.5 [M + H]<sup>+</sup>, C<sub>144</sub>H<sub>183</sub>N<sub>69</sub>NaO<sub>38</sub> requires = 3487.46, found 3509.5 [M + Ka]<sup>+</sup>, C<sub>144</sub>H<sub>183</sub>N<sub>69</sub>KO<sub>38</sub> requires = 3509.44, found 3525.4 [M + K]<sup>+</sup>, C<sub>144</sub>H<sub>183</sub>N<sub>69</sub>KO<sub>38</sub> requires = 3525.42. Additional synthetic and analytical details are described in the supporting information.

General Experimental Procedure for the Preparation of 3,5-disubstituted Isoxazoles (17) – Method A:<sup>[21]</sup> To a solution of *O*silylated hydroxamic acid 11 (1 equiv.) in anhydrous  $CH_2CI_2$  was added NEt<sub>3</sub> (3 equiv.) under an inert atmosphere of argon. This was followed by the dropwise addition of a 1 M solution of  $Tf_2O$  in  $CH_2CI_2$  (1.1 equiv.) at -40 °C. Once the addition was completed, the reaction mixture was allowed to stir for 1 h at 0 °C, after which alkyne 16 (8 equiv.) was added, and the resulting mixture stirred overnight (approx. 16 h) at r.t. Next, the solution was washed with  $H_2O$ . The organic layer was dried with anhydrous Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated to dryness in vacuo.<sup>[3]</sup> The residue was purified by silica gel column chromatography to afford desired isoxazole 17. With this procedure, we prepared cycloadducts 17a-d.

General Experimental Procedure for the Preparation of 3,5-disubstituted Isoxazoles (17) – Method B: To a solution of *O*-silylated hydroxamic acid 11 (1 equiv.) in anhydrous  $CH_2Cl_2$  was added NEt<sub>3</sub> (3 equiv.) under an inert atmosphere of argon. This was followed by the dropwise addition of a 1 M solution of  $Tf_2O$  in  $CH_2Cl_2$ (1.1 equiv.) at -40 °C. Once the addition was completed, the reaction mixture was allowed to stir for 3 min at -40 °C, after which it was cannulated batchwise (every 15 min over 45 min) at that temperature, onto neat alkyne 16 kept at r.t. (8 equiv.). The resulting mixture was stirred overnight (approx. 16 h) at r.t. Next, the solution was washed with H<sub>2</sub>O. The organic layer was dried with anhydrous Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated to dryness in vacuo. The residue was purified by silica gel column chromatography to afford desired isoxazole 17. With this procedure, we prepared cycloadducts 17a–n.

**5-Hexyl-3-phenylisoxazole (17a):** Synthesis according to Method A: Yield 49 % (23 mg) of desired product **17a** as a viscous light-yellow oil. Synthesis according to Method B: Yield 75 % (35 mg, viscous lightyellow oil).  $R_f = 0.58$  (CH<sub>2</sub>Cl<sub>2</sub>). <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = 7.79-$ 7.76 (m, 2H, CH), 7.44–7.42 (m, 3H, CH), 6.31 (s, 1H, CH), 2.77 (m, 2H, CH), 1.74–1.68 (m, 2H, CH), 1.40–1.29 (m, 6H, CH), 0.89 (t, J =7.1 Hz, 3H, CH), the proton assignment has been done by 2D analysis; <sup>13</sup>C NMR (100 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = 174.9$ , 162.6, 130.1, 129.9, 129.2, 127.1, 99.1, 31.9, 29.2, 27.9, 27.2, 22.9, 14.2; MS (ESI-HRMS): Found 230.1541 [M + H]<sup>+</sup>, C<sub>15</sub>H<sub>20</sub>NO requires = 230.1539. All other spectroscopic and analytical properties were identical to those reported in the literature.<sup>[34a]</sup>

**3,5-Diphenylisoxazole (17b):** Synthesis according to Method A: Yield 54 % (16 mg) of desired product **17b** as a white solid. Synthesis according to Method B: Yield 78 % (23 mg, white solid).  $R_f = 0.58$  (CH<sub>2</sub>Cl<sub>2</sub>). m.p. 137–139 °C; <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = 7.85–7.83$  (m, 4H, CH), 7.50–7.47 (m, 6H, CH), 6.88 (s, 1H, CH); <sup>13</sup>C NMR (100 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta = 170.7$ , 163.3, 130.6, 130.4, 129.6, 129.4, 129.3, 127.8, 127.1, 126.1, 97.9. **3,4,5-Triphenylisoxazole (17m), synthesis according to Method B:** Desired derivative **17m** was isolated by silica gel column chromatography (eluent: CH<sub>2</sub>Cl<sub>2</sub>), along with traces of an unidentified by-product. Further purification was attempted by means of preparative TLC plates (3 ×; eluent: CH<sub>2</sub>Cl<sub>2</sub>). However, **17m** could not be isolated pure. 6 mg of that mixture was obtained as a white solid, thus affording less than 15 % yield in **17m**.  $R_{\rm f}$  = 0.69 (CH<sub>2</sub>Cl<sub>2</sub>). <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  = 8.15 (m, CH), 7.52–7.44 (m, CH); MS (ESI-HRMS): Found 298.1225 [M + H]<sup>+</sup>, C<sub>2</sub>1H<sub>16</sub>NO requires = 298.1226.

**5-(4-Ethynylphenyl)-3-phenylisoxazole (17n), synthesis according to Method B:** Yield 18 % (7 mg) of product **17n** as a white solid.  $R_{\rm f}$  = 0.58 (CH<sub>2</sub>Cl<sub>2</sub>). m.p. 96–98 °C; <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  = 7.86–7.84 (m, 2H, *CH*), 7.80 (d, *J* = 8.6 Hz, 2H, *CH*), 7.60 (d, *J* = 8.6 Hz, 2H, CH), 7.49–7.47 (m, 3H, *CH*), 6.90 (s, 1H, *CH*), 3.26 (s, 1H, *CH*); <sup>13</sup>C NMR (100 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  = 169.8, 163.4, 133.1, 130.5, 129.3, 129.1, 127.9, 127.1, 126.0, 124.3, 98.7, 83.2, 79.5; IR (cm<sup>-1</sup>):  $\tilde{v}$  = 511.4, 543.2, 615.2, 627.1, 663.7, 692.7, 764.0, 819.0, 845.3, 916.6, 949.9, 1044.9, 1090.1, 1112.1, 1399.2, 1413.7, 1462.4, 1493.7, 2920.0, 3298.2; MS (ESI-HRMS): Found 246.0914 [M + H]<sup>+</sup>, C<sub>17</sub>H<sub>12</sub>NO requires = 246.0913.

VGVA Peptide-isoxazole conjugate (17o): To a solution of O-silylated hydroxamic acid of phenyl 11a (180 mg, 0.48 mmol) in anhydrous  $CH_2Cl_2$  (7.2 mL) was added NEt<sub>3</sub> (146 mg, 202  $\mu$ L, 1.44 mmol) under an inert atmosphere of argon. This was followed by the dropwise addition of a 1 M solution of  $Tf_2O$  in  $CH_2CI_2$  (528  $\mu$ L, 0.528 mmol) at –40 °C. Once the addition was completed, the reaction mixture was allowed to stir for 3 min at -40 °C, after which it was added to a suspension of resin-bound ethynyl-functionalized peptide 16i (100 mg, 0.048 mmol) in DMF (2 mL). The resulting mixture was shaken overnight (approx. 16 h) at 50 °C. The solution was then filtered and washed with DMF (5  $\times$  5 mL) and CH<sub>2</sub>Cl<sub>2</sub>  $(7 \times 5 \text{ mL})$ . The resulting crude was isolated, cleaved from the resin, analyzed and purified by RP-HPLC. The cleavage cocktail mixture used was TFA/H<sub>2</sub>O/EDT/TIPS, 94:2.5:2.5:1. The cleavage took place for 4 h, under an inert atmosphere of argon. Peptide 170 was isolated as a white solid, soluble in a mixture of  $H_2O/CH_3CN$ , 1:1 + 0.1 % TFA. HPLC retention time: 26.7 min. MS (MALDI-HRMS): Found 1305.6781  $[M + H]^+$ ,  $C_{61}H_{93}N_{16}O_{14}S$  requires = 1305.6778, found 1327.7  $[M + Na]^+$ ,  $C_{61}H_{92}N_{16}NaO_{14}S$  requires = 1327.66, found 1343.6  $[M + K]^+$ ,  $C_{61}H_{92}N_{16}KO_{14}S$  requires = 1343.63. Based on the analytical RP-HPLC chromatogram, it was calculated that 49 % con-

version was obtained, of which 41 % corresponded to desired cycloadded peptide **170**, and 8 % to unidentified subproducts. 51 % of starting acetylenic-peptide **16i** were recovered thereby resulting in 84 % yield of peptide–isoxazole conjugate. Percentages are given as area%. Additional synthetic and analytical details are described in the supporting information.

(AATT)<sub>3</sub> Lys PNA-isoxazole conjugate (17p): To a solution of O-silylated hydroxamic acid of phenyl 11a (19 mg, 0.040 mmol) in anhydrous CH<sub>2</sub>Cl<sub>2</sub> (50 µL) was added NEt<sub>3</sub> (12.2 mg, 16.6 µL, 0.12 mmol) under an inert atmosphere of argon. This was followed by the dropwise addition of a 1 M solution of Tf<sub>2</sub>O in CH<sub>2</sub>Cl<sub>2</sub> (44  $\mu$ L, 0.044 mmol) at -40 °C. Once the addition was completed, the reaction mixture was allowed to stir for 3 min at -40 °C, after which it was added to a suspension of resin-bound Cbz-protected ethynylfunctionalized PNA 16j (10 mg, 0.0041 mmol) in DMF (200 µL). The resulting mixture was shaken overnight (approx. 16 h) at 50 °C. The solution was then filtered and washed with DMF ( $5 \times 5$  mL) and  $CH_2Cl_2$  (7 × 5 mL). The resulting crude was isolated, cleaved from the resin and the Cbz groups deprotected. Resulting deprotected PNA 17p was analyzed and purified. PNA 17p was isolated as a white solid, soluble in a mixture of H<sub>2</sub>O/CH<sub>3</sub>CN, 1:1 + 0.1 % TFA. HPLC retention time: 18.1 min. MS (MALDI-HRMS): Found 3606.6648 [M + H]<sup>+</sup>, C<sub>151</sub>H<sub>189</sub>N<sub>70</sub>O<sub>39</sub> requires = 3606.4952, found 3628.6714 [M + Na]<sup>+</sup>,  $C_{151}H_{188}N_{70}NaO_{39}$  requires = 3628.4772, found 3644.6257  $[M + K]^+$ ,  $C_{151}H_{188}N_{70}KO_{39}$  requires = 3644.4511. **17p** was formed in 43 % (%area of desired cycloadduct in the RP-HPLC chromatogram). Additional synthetic and analytical details are described in the supporting information.

5-Hexyl-3-phenyl-4,5-dihydroisoxazole (19): To a solution of Osilylated hydroxamic acid of phenyl 11a (75 mg, 0.2 mmol) in anhydrous CH<sub>2</sub>Cl<sub>2</sub> (3 mL) was added NEt<sub>3</sub> (60.7 mg, 83.6 µL, 0.6 mmol) under an inert atmosphere of argon. This was followed by the dropwise addition of a 1 M solution of Tf<sub>2</sub>O in CH<sub>2</sub>Cl<sub>2</sub> (220 µL, 0.22 mmol) at -40 °C. Once the addition was completed, the reaction mixture was allowed to stir for 1 h at 0 °C, after which 1-octene 18 (179.6 mg, 252 µL, 1.6 mmol) was added, and the resulting mixture stirred overnight (approx. 16 h) at r.t. Next, the solution was washed with  $H_2O$  (2  $\times$  1 mL). The organic layer was dried with anhydrous Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated to dryness in vacuo. The residue was purified by silica gel column chromatography (eluent:  $CH_2Cl_2$ ), yielding **19** (36.6 mg, 79 %) as a white solid.  $R_f = 0.56$ (CH<sub>2</sub>Cl<sub>2</sub>). m.p. 49-52 °C; <sup>1</sup>H NMR (400 MHz, CD<sub>2</sub>Cl<sub>2</sub>, \*denotes rotamer peaks):  $\delta$  = 7.65–7.62 (m, 2H, CH), 7.39–7.37 (m, 3H, CH), 4.67– 4.65 (m, 1H, CH), 3.40-3.33 & 2.97-2.90\* (m, 2H, CH), 1.78-1.70 & 1.62-1.55\* (m, 2H, CH), 1.47-1.24 (m, 8H, CH), 0.89-0.85 (t, J = 7.0 Hz, 3H, CH), the proton assignment has been done by 2D analysis; <sup>13</sup>C NMR (100 MHz, CD<sub>2</sub>Cl<sub>2</sub>):  $\delta$  = 156.7, 130.5, 130.1, 129.0, 126.8, 81.9, 40.2, 35.7, 32.1, 29.5, 25.9, 22.9, 14.2. All other spectroscopic and analytical properties were identical to those reported in the literature.<sup>[20c]</sup>

(4-(Methoxycarbonyl)phenyl)boronic acid (23): To a solution of 4-carboxyphenyl boronic acid 24 (1 g, 6.03 mmol) in anhydrous MeOH (17.4 g, 22 mL, 543 mmol) was slowly added SOCl<sub>2</sub> (4.5 g, 2.7 mL, 37.39 mmol) under an inert atmosphere of argon. The resulting mixture was stirred for 2 h 30 at 50 °C, after which it was concentrated to dryness in vacuo. The compound was also dried under high vacuum to remove any residual trace SOCl<sub>2</sub>. The residue was dissolved in EtOAc (50 mL) and washed with brine (20 mL). The aqueous phase was extracted with EtOAc (2 × 30 mL) and the combined organic phases dried with anhydrous MgSO<sub>4</sub>, filtered and concentrated to dryness in vacuo to yield 23 as a white solid (1 g, 92 %). No further purification was required. m.p. 232–233 °C; <sup>1</sup>H

NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  = 8.29 (d, *J* = 8.0 Hz, 2H, *CH*), 8.17 (d, *J* = 8.0 Hz, 2H, *CH*), 3.98 (s, 3H, *CH*), BOH proton signals were not observed; <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>):  $\delta$  = 167.1, 135.7, 134.0, 133.6, 129.1, 52.5. All other spectroscopic and analytical properties were identical to those reported in the literature.<sup>[39,47]</sup>

5'-(4-Carboxyphenyl)-[1,1':3',1"-terphenyl]-4,4"-dicarboxylic acid (26): Tri-ester 27 (370 mg, 0.77 mmol) was dissolved in a mixture of THF/MeOH, 1:1 (14 mL), and 7 mL of 4.8 M aq. solution of NaOH (1.344 g, 33.6 mmol) added at 0 °C. The reaction mixture was stirred overnight (approx. 16 h) at r.t., after which the solvents were evaporated in vacuo. The residue was solubilised in H<sub>2</sub>O (minimum amount, i.e. 7 mL) and the resulting solution acidified to pH ca. 2 with 1 M aq. solution of HCl. The resulting white precipitate was filtered, collected, resuspended in H<sub>2</sub>O (5 mL), sonicated and filtered throughce more. Through this procedure, NaCl salts were washed out. The white solid was collected and dried under high vacuum (233 mg, 70 % yield in 26). m.p. 316-319 °C; <sup>1</sup>H NMR (400 MHz,  $[D_6]DMSO$ :  $\delta = 8.09$  (s, 3H, CH), 8.06 (s, 12H, CH), COOH proton signals were not observed; <sup>13</sup>C NMR (100 MHz, [D<sub>6</sub>]DMSO):  $\delta$  = 167.1, 143.8, 140.8, 130.0, 129.9, 127.4, 125.6. All other spectroscopic and analytical properties were identical to those reported in the literature.<sup>[41,48]</sup>

Dimethyl 5'-(4-(methoxycarbonyl)phenyl)-[1,1':3',1"-terphenyl]-4,4"-dicarboxylate (27): Na<sub>2</sub>CO<sub>3</sub> (1.01 g, 9.53 mmol) 4-methoxycarbonylphenylboronic acid 23 (1.28 g, 7.15 mmol), 1,3,5-tribromobenzene 25 (500 mg, 1.59 mmol) and [Pd(PPh<sub>3</sub>)<sub>4</sub>] (184 mg, 0.159 mmol) were weighed into a 10-20 mL microwave flask, under an inert atmosphere of argon. A degassed mixture of toluene/EtOH, 1:1 (17 mL) was then added to the solids (Note: toluene and EtOH are degassed in two different two-neck flasks; simple argon bubbling (with two argon balloons and two thick needle outlets), for 45 min is enough to degas the solvents for this reaction; drops of water are added in EtOH). The resulting mixture was stirred for 5 min before being heated at 110 °C for 4 h under microwave conditions (the pressure rose up to 8 bars). The solution was then diluted with  $CH_2Cl_2$  (250 mL) and extracted with  $H_2O$  (3 × 100 mL) and brine  $(1 \times 100 \text{ mL})$ . The organic phase was dried with anhydrous MqSO<sub>4</sub>, filtered and concentrated to dryness in vacuo. The residue was purified by silica gel column chromatography (eluent: Cy to Cy/ EtOAc, 4:6) yielding 48 % of desired product 27 (370 mg) as a white solid.  $R_{\rm f} = 0.45$  (Cy/EtOAc, 4:6). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta = 8.16$ (d, J = 8.2 Hz, 6H, CH), 7.86 (s, 3H, CH), 7.77 (d, J = 8.5 Hz, 6H, CH), 3.96 (s, 9H, CH).<sup>[40,49]</sup> The next step, i.e. saponification, was performed on the whole batch, without further characterizations of triester derivative 27.

 Synthesis of 3,5-Disubstituted Isoxazoles through a 1,3-Dipolar Cycloaddition Reaction between Alkynes and Nitrile Oxides Generated from O-Silylated Hydroxamic Acids

The regioselective synthesis of 3,5-disubstituted isoxazoles through a 1,3dipolar cycloaddition reaction between alkynyl dipolarophiles and in situ formed nitrile oxide dipoles. This approach provides a tolerance to a large variety of substrates due to the mild, metal-free and oxidant-free reaction conditions. The method can be used to introduce fluorescent as well as peptidic and PNA substituents.
