Abstract

Sarcophytonolides are cembranolide diterpenes isolated from the soft corals of genus *Sarcophyton*. Unified total synthesis of sarcophytonolides C, E, F, G, H, and J and isosarcophytonolide D was achieved. The synthetic routes feature NaHMDS- or SmI₂-mediated fragment coupling, alkoxycarbonylallylation, macrolactonization, and transannular ring-closing metathesis. These total syntheses led to the absolute configurational confirmation of sarcophytonolide H, elucidation of sarcophytonolides C, E, F, and G, and revision of sarcophytonolide J and isosarcophytonolide D. We also evaluated the antifouling activity and toxicity of the synthetic sarcophytonolides H and J and their analogues as well as the cytotoxicity of the synthetic sarcophytonolides and the key synthetic intermediates.

Introduction

Corals are an important group of marine invertebrates and have proven to be a rich source of secondary metabolites with a diversity of the chemical structure and biological activity.¹ Among natural products isolated from soft corals, cembranolide diterpenes² exhibit a variety of biological activities such as antibacterial,³ antifouling,⁴ antiviral,⁵ cytotoxic,⁶ ichthyotoxic,⁷ and protein tyrosine phosphatase 1B inhibitory activities.⁸ In addition, it has been reported that cembranoid diterpens are implicated in defense of soft corals against predators and

competition between soft corals and hard corals.^{1a,9}

Guo and co-workers have isolated sarcophytonolides, cembranolide diterpenes, from the soft corals of the genus Sarcophyton collected at Hainan Province in China since 2005.^{8,10} These natural products have a 14-membered carbon skeleton and butenolide unit as common structures as described in Figure 1. The gross structure of sarcophytonolide C (1) was determined by the 2D NMR analysis and comparison of its NMR data with those of brassicolide (5), of which the relative configuration was assigned by X-ray crystallographic analysis.^{6b,10a} Although the relative stereochemistries at the C1 and C2 positions of 1 were elucidated by NOE observations between H-2 and H-15, the configuration at the C8 position, which is a chiral center remote from the C1 and C2 positions, could not be determined. The relative configurations at the C6 and C8 positions of sarcophytonolide E(2) were assigned by NOE correlations of H-6/H₃-19 and analysis of coupling constants and splitting patterns of H₂-5 in the model wherein a hydrogen bond between the hydroxy and the carbonyl groups is formed.^{10b} The relative configurations of sarcophytonolides F (3) and G (4), which have the C7/C8 trisubstituted alkenes and the C6 stereoisomeric relationship, were revealed by NOE experiments and analysis of their coupling constants of H₂-5.^{10b} The relative stereochemistry of sarcophytonolide H (6) was clarified by the similarity of 1 H and 13 C NMR data between 6 and 3 and NOE observations such as those of H-2/H-14 and H-2/H-15.^{10b} The absolute configuration of **6** was determined by applying the modified Mosher method.¹¹ The relative stereochemistry of sarcophytonolide D (7) possessing the α -oriented acetoxy group at the C14 position was elucidated by NOE experiments.^{10a,12} The relative stereochemistries at the C1, C2, and C14 positions of sarcophytonolides I (8), 10c J (9), 10c and isosarcophytonolide D $(10)^{10d}$ were assigned by the analogy of their ¹H and ¹³C NMR data to those of sarcophytonolide D (7), whereas the C8 stereochemistry of 9 has remained to be clarified as in the case of sarcophytonolide C (1). Among these sarcophytonolides, sarcophytonolides H (6) and J (9) display the antifouling activity against the cypris larvae of the barnacle Balanus (Amphibalanus) amphitrite with EC_{50} values of 5.98¹³ and 7.50 µg/mL,¹⁴ respectively. Interestingly, there is also a report wherein sarcophytonolide J (9) has no inhibitory activity against the larval settlement of the same barnacle.¹³ In 2013, as a preliminary communication, we reported the total synthesis of two possible diastereomers of sarcophytonolide C (1), which resulted in the absolute configurational determination of this natural product.^{15a,16} In 2016, we also reported the total synthesis of sarcophytonolide H (6) and isosarcophytonolide D (10, proposed structure), which culminated in the absolute stereochemical confirmation of 6 and revision of 10.^{15b} In this full paper, we disclose the unified total synthesis of sarcophytonolides C, E, F, G, H, and J and isosarcophytonolide D by using NaHMDS- or SmI₂-mediated fragment coupling, alkoxycarbonylallylation, macrolactonization, and transannular ring-closing metathesis (RCM) as key steps. These total syntheses culminated in the absolute stereochemical confirmation of sarcophytonolide H, determination of sarcophytonolides C, E, F, and G, and revision of sarcophytonolide J and isosarcophytonolide

D. Furthermore, we report the cytotoxicity of the synthetic sarcophytonolides and the key synthetic intermediates, and the antifouling activity and toxicity of the synthetic sarcophytonolides H and J and their analogues.

Results and Discussion

Retrosynthetic Analysis of 1a and 1b. Toward the absolute configurational determination of natural sarcophytonolide C (1), we decided to synthesize **1a** and **1b** (Scheme 1), which are two possible diastereomers of this natural product. In the retrosynthetic analysis, we designed hydroxycarboxylic acids **11a** and **11b** as the key synthetic intermediates to construct the cembranolide frameworks of **1a** and its C8 epimer **1b** by macrolactonization¹⁷ and subsequent transannular RCM¹⁸, respectively.¹⁹ We hypothesized that the macrolactonization precursors **11a**,**b** could possibly supplied by the connection of sulfone **12**, allylic bromides **13a** and **13b**, and 2-alkoxycarbonyl allylic metal reagent **14**. The chiral pool synthesis starting from (*S*)-and (*R*)-citronellols could provide the allylic bromides **13a**,**b**, respectively. We envisioned that this retrosynthetic bond-disconnection could be also applied to the synthesis of C6 hydroxylated and/or C14 acetoxylated sarcophytonolides. Moreover, the use of geraniol and nerol instead of citronellol as starting materials would potentially lead to the total synthesis of

sarcophytonolides bearing the C7/C8 trisubstituted alkene moieties.

Scheme 1. Retrosynthetic Analysis of 1a and 1b

Total Synthesis of Two Possible Diastereomers 1a and 1b of Sarcophytonolide C (1). First, we investigated the enantioselective synthesis of sulfone 20 (Scheme 2). Monosilylation of *cis*-2-butene-1,4-diol with *tert*-butyldimethylsilyl chloride (TBSCl) followed by Sharpless asymmetric epoxidation²⁰ with (+)-diethyl tartrate (DET) gave epoxy alcohol 15 in 86% yield. The enantiomeric ratio of 17:1 was assigned by the ¹H NMR spectra of (*S*)- and (*R*)-α-methoxy-β-(trifluoromethyl)phenylacetyl (MTPA) esters prepared from 15. The epoxide 15 reacted with isopropenylmagnesium bromide in the presence of CuBr·SMe₂²¹ to provide 1,3-diol 16, regioselectively.²² Hydrogenation of the alkene 16 with (Ph₃P)₃RhCl and subsequent selective thioetherification of diol 17²³ with (PhS)₂/*n*-Bu₃P afforded sulfide 18. After the alcohol 18 was protected as the TBS ether, sulfide 19 was oxidized to furnish the sulfone 20.²⁴

Scheme 2. Synthesis of Sulfone 20

Next, connection of the sulfone **20** and allylic bromides **21a** and **21b**, which were synthesized from (*S*)- and (*R*)-citronellols,²⁵ was examined (Scheme 3). Thus, the anion derived from **20** with sodium hexamethyldisilazide (NaHMDS) was treated with the optically active **21a** and **21b** to produce the coupling products **22a** and **22b** in 88% and 91% yields, respectively. Reductive removal of the sulfonyl groups of **22a,b** under Birch conditions,²⁶ wherein the pivaloyl (Piv) groups were partially removed,²⁷ and protection of the resulting alcohols afforded the corresponding pivalates. The primary TBS ethers were selectively deprotected with camphorsulfonic acid (CSA) to give alcohols **23a** and **23b**. Oxidation of **23a,b** with 2,2,6,6-tetramethylpiperidinyloxyl (TEMPO)/PhI(OAc)₂²⁸ and subsequent Wittig reaction yielded alkenes **24a** and **24b**. Reductive deprotection of the pivalates **24a,b** was carried out with diisobutylaluminum hydride (DIBAL-H) to provide alcohols **25a** and **25b**.

Scheme 3. Synthesis of Alcohols 25a and 25b

We next tried to synthesize the macrolactonization precursors **30a** and **30b** as shown in Scheme 4. The alcohols **25a**,**b** were oxidized with TEMPO/PhI(OAc)₂²⁸ and the resulting aldehydes were treated with ethyl (2-bromomethyl)acrylate (**26**)/Zn dust in THF/aqueous NH₄Cl²⁹ to furnish the desired homoallylic alcohols **27a** and **27b** in 79% and 93% yields in two steps as 1:1 diastereomeric mixtures, respectively. After the resulting hydroxy groups of **27a**,**b** were protected as the methoxymethyl (MOM) ethers, the TBS moieties of **28a** and **28b** were removed with tetrabutylammounium fluoride (TBAF) to give alcohols **29a** and **29b**. Alkaline hydrolysis of the ethyl esters **29a**,**b** with LiOH·H₂O afforded hydroxycarboxylic acids **30a** and **30b**.

Scheme 4. Synthesis of Hydroxycarboxylic Acids 30a and 30b

With the macrolactonization precursors **30a** and **30b** in hand, we next investigated the construction of the cembranolide framework and completion of the total synthesis. Thus, the hydroxycarboxylic acids **30a**,**b** were subjected to the Shiina macrolactonization conditions with 2-methyl-6-nitrobenzoic anhydride (MNBA)^{17,30} to give 15-membered macrolactones **31a** and **31b** in 85% and 78% yields, respectively (Scheme 5). After the MOM ethers **31a**,**b** were deprotected with BF₃·OEt₂/Me₂S,³¹ transannular RCM¹⁸ of **32a** and **32b** was conducted by using the second-generation Hoveyda–Grubbs catalyst (**33**)³² to produce butenolides **34a**

and 34b.^{33,34} In these reactions, the prolonged reaction time caused the formation of byproducts, therefore the starting materials **32a** and **32b** were recovered in 38% and 37% yields, respectively. Finally, TPAP (tetra-*n*-propylammonium perruthenate) oxidation³⁵ of **34a**,**b** provided the target molecules **1a** and **1b** in 27% (43% based on recovered **32a**) and 30% (48% based on recovered **32b**) in two steps, respectively.³⁶

Absolute Configuration of Sarcophytonolide C (1). Having succeeded in the total synthesis of 1a and 1b, we analyzed their 2D NMR spectra and assigned the signals in their ¹H and ¹³C NMR spectra. Tables 1 and 2 depict the chemical shifts and their differences of natural sarcophytonolide C (1)^{10a} and the synthetic products 1a and 1b in the ¹H and ¹³C NMR spectra, respectively. The ¹H and ¹³C NMR data of 1a were in excellent agreement with those of natural sarcophytonolide C (1), meanwhile the ¹H and ¹³C NMR data of 1b were clearly different from those of natural product 1. It was found that there were critical differences of the chemical shifts between the natural product and the synthetic 1b at the C7, C8, and C9 positions in the ¹H NMR data and at the C9, C10, and C11 positions in the ¹³C NMR data. The sign of specific rotation of the synthesized 1a, $[\alpha]_D^{29} = +92.2$ (c = 0.19, CHCl₃), was same as that of the data reported for the natural product, $[\alpha]_D^{20} = +31.0$ (c = 0.20, CHCl₃).^{10a,37} Therefore, the absolute configuration of sarcophytonolide C (1) isolated from nature was clarified to be 1*S*, 2*S*, and 8*S* as shown in 1a.

Calculations for **1a** and **1b** were carried out using density functional theory (DFT) calculations at the ω B97X-D/6-31G* level. Conformational analysis and geometry optimization of **1a** and **1b** were performed with the package SPARTAN'16 (Wavefunction Inc., Irvine, CA). As described in Figure 2, in the calculated most stable conformer of **1a**, the

C8 carbon is located more inside the macrocycle structure in comparison with the case of the most stable conformer of **1b**, which seems to make the distances between C1/C2 and C8 in **1a** shorter than those in **1b**. This conformational difference of **1a** and **1b** may have resulted in the deviation in their NMR data in spite of the C8 stereocenter remote from the C1 and C2 positions.

Figure 2. Calculated lowest-energy conformers of 1a (above) and 1b (below).

Total Synthesis of Sarcophytonolide E (2). Next, we examined the stereoselective synthesis of sarcophytonolide E (2) possessing the chiral alcohol moiety at the C6 position. First, we surveyed the reaction conditions in asymmetric alkoxycarbonylallylation of the aldehyde prepared from the alcohol 25a and it was proven that treatment of the aldehyde with chiral allylic boronate 35^{38} in toluene at room temperature provided the desired alcohol 36 in a 4.4:1 diastereomeric ratio (Scheme 6).²² Further transformation from 36 to sarcophytonolide E (2) was identical to that used for the total synthesis of 1a and 1b. Thus, MOM protection of the resulting hydroxy group of 36 and removal of the TBS moiety afforded alcohol 37. Alkaline hydrolysis of the ethyl ester 37 followed by Shiina macrolactonization^{17,30} yielded 15-membered macrolactone 38. Deprotection of the MOM ether 38 with BF₃·OEt₂/Me₂S³¹ and subsequent transannular RCM¹⁸ produced sarcophytonolide E (2).³⁹ The ¹H and ¹³C NMR data and the specific rotation of the synthesized 2 were in good accordance with those of the natural product,^{10b,40} which elucidated the absolute stereochemistry of natural sarcophytonolide E to be that described in 2.

Total Synthesis of Sarcophytonolides F (3) and G (4). Having completed the total synthesis of 1a, 1b, and 2 bearing the chiral centers at the C8 positions, we next investigated the stereoselective synthesis of sarcophytonolides F (3) and G (4) with the C7/C8 (*E*)-trisubstituted alkene portions. First, as shown in Scheme 7, the synthesis of allylic bromide 41, which is a coupling partner of the sulfone 20, was carried out. Protection of geraniol with PivCl gave pivalate 39. Treatment of 39 with SeO₂/TBHP/salicylic acid⁴¹ provided the mixture of allylic alcohol 40 and the corresponding α , β -unsaturated aldehyde. The mixture was treated with NaBH₄ to afford the allylic alcohol 40 in 57% yield in two steps. The structure of 40 was confirmed by NOE observations of H₂-1/H-3. The allylic alcohol 40 was converted to the allylic bromide 41 with CBr₄/PPh₃.

We next tried the connection of the sulfone 20 and the allylic bromide 41, and transformation to sarcophytonolides F (3) and G (4). Thus, the sulfone 20 was coupled with the allylic bromide 41 in the presence of NaHMDS to afford the desired product 42 (Scheme 8). After deprotection of the pivalate 42 with DIBAL-H, reductive desulfonylation was conducted under Birch conditions²⁶ to give alcohol **43** in 79% yield in two steps.⁴² The alcohol 43 was converted to alkene 45 by the following sequence: 1) protection as the pivalate, 2) selective removal of the primary TBS moiety. 3) TEMPO oxidation²⁸ of alcohol 44, 4) Wittig methylenation, and 5) deprotection of the pivalate. The aldehyde, synthesized from the alcohol 45, was treated with the chiral allylic boronate 35^{38} to result in the diastereoselective formation of alcohol 46 in a 17:1 ratio.²² After protection of the alcohol 46 and subsequent desilvlation, hydrolysis of 47 and Shiina lactonization^{17,30} were carried out to afford macrolactone 48. Transannular RCM^{18} of the tetraene 48 proceeded smoothly in the presence of the second-generation Hoveyda–Grubbs catalyst (33),³² wherein two trisubstituted alkene portions of 48 were inert to the reaction conditions, to produce the corresponding butenolide in 76% yield. Finally, the MOM protecting group was cleaved with trimethylsilyl iodide (TMSI)/HMDS^{43,44} to furnish sarcophytonolide F (3). We next tried to transform sarcophytonolide F (3) to sarcophytonolide G (4) by stereoinversion at the C6 position. Mitsunobu reaction⁴⁵ of **3** with *p*-nitrobenzoic acid/diethyl azodicarboxylate (DEAD)/Ph₃P⁴⁶ followed by alkaline hydrolysis with Na₂CO₃ in MeOH provided sarcophytonolides G (4) and F (3) in 31% and 13% yields in two steps, respectively. The formation of 3 was caused by the esterification with stereoretention in the first step.⁴⁷ Changing reaction temperature and carboxylic acid in Mitsunobu reaction⁴⁵ could not improve the chemical yield of **4**. Therefore, we next examined the stereoselective reduction of the ketone. Treatment of the allylic alcohol 3 with Dess-Martin periodinane⁴⁸ gave α , β -unsaturated ketone 49. Corey-Bakshi-Shibata (CBS) reduction⁴⁹ using (*R*)-Me-CBS/BH₃·SMe₂ was applied to 49 to result in the formation of 4 and 3 in a 1:1 diastereometric ratio. After investigation of the reaction conditions, fortunately, Luche reduction conditions⁵⁰ in MeOH/CH₂Cl₂ was found to be effective and sarcophytonolide G (4) was produced in 72% yield as a sole product. Although the detailed conformational analysis of 49 was not conducted, the stereochemical outcome in this Luche reduction is understandable by the formation of chelation structure as described in Figure 3. In this structure, the proton of methanol could coordinate to two carbonyl oxygens at the C6 and C18 positions and hydride could approach from the outside of the macrocyclic structure. Detailed comparison of the NMR data and specific rotations between the natural products^{10b} and the synthetic products in 3 and 4 revealed the absolute configurations of natural sarcophytonolides F and G to be those shown in **3** and **4**, respectively.⁴⁰

Figure 3. Plausible rationale for the configurational outcome in Luche reduction of ketone 49. Total Synthesis of Sarcophytonolide H (6). We next focused on the total synthesis of sarcophytonolides possessing the acetoxy groups at their C14 positions. First, we tried to synthesize sarcophytonolide H (6). We initially envisioned that the oxygen-functional group at the C14 position could be introduced by oxidative desulfurization of the sulfone 42, which is the synthetic intermediate of the total synthesis of sarcophytonolides F (3) and G (4). Actually, deprotonation of 42 with n-BuLi or lithium diisopropylamide (LDA) and subsequent treatment with Davis oxaziridine $(50)^{51}$ or bis(trimethylsilyl)peroxide⁵² did not produce the desired ketone 51 (Scheme 9). Therefore, we planned to introduce the C14 oxymethyne moiety by other fragment couplings. Our synthesis of the C14 stereoisomers 53a and 53b, wherein the SmI₂-mediated reaction⁵³ was used as the fragment coupling, is described in Scheme 10. Selective acetylation of the diol 16 followed by TBS protection of the resulting secondary alcohol gave the corresponding silvl ether. Reductive deprotection of the acetate with DIBAL-H afforded the alcohol, which was oxidized to aldehyde 52 with TEMPO/PhI(OAc)₂.²⁸ The aldehyde **52** was connected with the allylic bromide **41** by using $\text{SmL}_2^{53,54}$ to furnish the desired α -adducts **53a** and **53b** in 53% and 40% yields, respectively. It is noteworthy that the coupling was successful by using 1.2 equiv of the allylic bromide 41 to the aldehyde 52 and the corresponding γ -allylated product was not formed at all.⁵⁵ The observed NOEs of H-11/H2-13 of 53a and 53b confirmed the geometries at their C11/C12 alkene portions, respectively. The stereochemistry at the C14 position of 53a was determined by the modified Mosher method.^{11,40}

ACS Paragon Plus Environment

Further transformation toward the total synthesis of sarcophytonolide H (6) is depicted in Scheme 11. Thus, protection of the hydroxy group of 53a with MOMCl and subsequent selective removal of the primary TBS moiety gave the corresponding alcohol. Introduction of the terminal alkene portion followed by deprotection of the obtained pivalate 54 afforded alcohol 55. TEMPO oxidation²⁸ of 55 and reaction of the aldehyde with the chiral boronate 35^{38} provided the desired allylated product 56 in 88% yield in two steps in a diastereometric ratio of 13:1. After the C6 hydroxy group of 56 was protected as the *p*-methoxybenzyl (PMB) ether, the TBS ether underwent deprotection and hydrolysis of the ester to yield hydroxycarboxylic acid 58. Shiina macrolactonization^{17,30} and subsequent transannular RCM¹⁸ were successfully performed to produce the corresponding butenolide. The obtained MOM ether was selectively deprotected with HCl in *i*-PrOH⁵⁶ to provide alcohol **60**. Finally, acetylation of the alcohol 60 and removal of the PMB moiety with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) took place to furnish sarcophytonolide H (6). The synthetic sarcophytonolide H (6) was in full agreement with the natural product in the ¹H and ¹³C NMR data and the specific rotation.^{10b,40} Therefore, the absolute configuration of natural sarcophytonolide H was confirmed as shown in 6.

Total Synthesis and Structural Revision of Isosarcophytonolide D. We next investigated synthesis of the proposed structure 10 of isosarcophytonolide D with the 14R stereochemistry. Thus, as shown in Scheme 12, the alcohol 53b was converted to 10 in 15 steps by a synthetic route similar to that used toward the total synthesis of sarcophytonolide H (6).⁵⁷ Having synthesized the proposed structure 10 of isosarcophytonolide D, we analyzed the 2D NMR data of the synthetic product 10. As a result, the significant differences in the ¹H and ¹³C NMR data between natural isosarcophytonolide D^{10d} and the synthesized **10** were observed.⁴⁰ The detailed comparison revealed that the chemical shift deviations were especially critical around the C14 position (Figure 4). We also considered that the stereochemistries at the C1 and C2 positions of isosarcophytonolide D would be same as those of other sarcophytonolides. Therefore, we predicted the correct structure of isosarcophytonolide D isolated from nature to be that drawn in **68**, which is the C14 stereoisomer of **10** (Scheme 13). The predicted structure 68 was synthesized by oxidation of the synthetic sarcophytonolide H (6) with Dess-Martin periodinane.⁴⁸ As anticipated, the ¹H and ¹³C NMR data and the specific rotation of the synthetic **68** matched those of the natural product.^{10d,40} Therefore, the absolute configuration of natural isosarcophytonolide D was reassigned to be that shown in 68.⁵⁸

Figure 4. Deviations of the ¹³C NMR chemical shifts between natural isosarcophytonolide D and the synthetic product **10** ($\Delta \delta = \delta_N - \delta_{10}$ in ppm). N = natural product. The x and y axes represent the carbon number and $\Delta \delta$, respectively.

Structural Prediction. Total and Structural Determination of Synthesis, Sarcophytonolide J. As noted in Introduction, the relative configurations at the C1, C2, and C14 positions of natural sarcophytonolides I (8), J (9), and isosarcophytonolide D (10) were determined by the similarity of their NMR data to those of sarcophytonolide D (7). This way of structural assignment and the stereochemical revision at the C14 position of isosarcophytonolide D indicate that the C14 stereochemistries of sarcophytonolides D (7), I (8), and J (9), which were originally assigned as 14R, should be also reexamined. Therefore, we next decided to verify the stereostructure of sarcophytonolide J (9, Figure 5a), of which the C8 configuration was not identified. First, in order to predict the C14 stereochemistry of sarcophytonolide J, we compared the ¹H and ¹³C NMR data of natural sarcophytonolide J^{10c} with those of the synthetic products 68 (revised structure of isosarcophytonolide D) and 10 (C14 epimer of **68**).⁴⁰ Deviations of the ¹³C NMR chemical shifts at the C1, C2, C13, and C14 positions between natural sarcophytonolide J and the synthetic products 68 and 10 are graphically depicted in Figure 5b. From these comparisons, it was found that the chemical shift differences between natural sarcophytonolide J and 68 were smaller than those between natural sarcophytonolide J and 10. In addition, for the prediction of the C8 stereochemistry of sarcophytonolide J, the ¹H and ¹³C NMR data between natural sarcophytonolide J^{10c} and the synthetic products **1a** (sarcophytonolide C) and **1b** (C8 epimer of **1a**) were compared.⁴⁰ As a result, it was elucidated that the chemical shift characteristics at the C7 to C10 positions of 1a were more similar to those of **1b**. Taken together, we could propose the predicted structure **69** of sarcophytonolide J (Figure 6), which bears the 8S and 14S absolute configurations same as those of 1a and 68.

Figure 5. (a) Structures of **9**, **68**, **10**, **1a**, and **1b**. (b) Deviations of the ¹³C NMR chemical shifts between natural sarcophytonolide J and the synthetic products ($\Delta \delta = \delta_N - \delta_S$ in ppm). N = natural product. S = synthetic product. The x and y axes represent the carbon number and $\Delta \delta$, respectively.

Scheme 14. Total Synthesis of the Predicted Structure 69 of Sarcophytonolide J

In order to confirm our stereostructural prediction of sarcophytonolide J as discussed above, we commenced the total synthesis of the predicted structure **69**. Sequence of the transformation toward **69** was similar to that used toward the total synthesis of sarcophytonolide H (**6**). Thus, SmI₂-mediated reaction of the aldehyde **52** and the allylic bromide **21a** gave the desired product **70a** and its C14 epimer **70b** in 29% and 40% yields, respectively (Scheme 14). The absolute stereochemistry at the C14 position of **70a** was verified by its derivatization and NOE experiments.⁴⁰ Subsequently, the alcohol **70a** was transformed to our predicted structure **69** of sarcophytonolide J in overall 16 steps. As expected, the synthetic **69** provided the ¹H and ¹³C NMR data and the specific rotation which were identical to those reported for natural sarcophytonolide J.^{10c,40} These findings clearly revealed that our stereochemical prediction of sarcophytonolide J is correct and this natural product possesses the 8*S* and 14*S* absolute configurations as shown in **69**.

Cytotoxicity of the Synthetic Products. Having successfully completed the total synthesis and established the stereostructures of sarcophytonolides, we next turned our attention to assessment of the biological activity of the synthetic products. First, we evaluated the growth-inhibitory activity by using the MTT assay with HL60 human leukemia cells. The cells were treated in 96-well plates with various concentrations of the synthetic compounds for 72 h. As described in Table 3, interestingly, the synthetic sarcophytonolide C (1a) was inactive, whereas 8-epi-sarcophytonolide C (1b) inhibited the growth of the cells with an IC_{50} value of 18.9 μ M, which indicates that the activity is affected by the C8 stereochemistries. Compared to **1a**, **1b** was observed to be more soluble in water, which may also contribute to the growth-inhibitory activity. Sarcophytonolide E(2), which possesses the C6 alcohol moiety, exhibited the activity with an IC₅₀ value of 33.0 μ M. Sarcophytonolide F (3) bearing the C7/C8 trisubstituted alkene group showed the activity similar to that of 2 (IC₅₀ = 35.9 μ M). Introduction of the C14 acetoxy moiety was found to lower the inhibitory activity by comparing IC₅₀ values of sarcophytonolides F (3, 35.9 μ M) and H (6, 53.5 μ M). Since 8-epi-sarcophytonolide C (1b) was the most active among five sarcophytonolides, the key synthetic intermediates of **1b** were next biologically evaluated. The cytotoxic activity of the butenolide construction precursor **32b** (IC₅₀ = 13.7 μ M) was slightly improved in comparison with that of 1b. The macrolactonization precursor 30b and the alcohol 25b retained the activity, while their activities were decreased to IC₅₀ values of 55.8 and 24.0 μ M, respectively.

Antifouling Activity and Toxicity of the Synthetic Products. Since sarcophytonolides H (6) and J (69) which were isolated from nature are reported to be antifouling active against the cypris larvae of barnacle *Balanus (Amphibalanus) amphitrite*,^{13,14} we next evaluated the antifouling activity⁵⁹ and toxicity of the synthetic sarcophytonolides H (6) and J (69) and their analogues against the cypris larvae of the same barnacle. The larvae were treated in 24-well polystyrene plates with various concentrations of the synthetic compounds in the dark for 96 h and the results are summarized in Table 4. The synthetic sarcophytonolide H (6) displayed the antifouling activity with an EC₅₀ value of 3.36 µg/mL, which was in good agreement with that of the natural product (5.98 µg/mL).¹³ Diol **79**⁶⁰ retained the antifoulant activity (EC₅₀ = 3.08 µg/mL), which indicates the acetyl group of **6** has little influence on this activity. The antifouling activity of the butenolide construction precursor **80**⁶⁰ was marginally increased in comparison with those of **6** and **79** (EC₅₀ = 1.61 µg/mL). The hydroxycarboxylic acid **58** turned out to be antifouling active (EC₅₀ = 3.27 µg/mL), while the alkoxycarbonylallylation precursor **55** exhibited no antifouling activity. Furthermore, the toxicity was also evaluated

and it was found that **58** was weak toxic (LC₅₀ = 19.4 µg/mL) and other compounds **6**, **79**, **80**, and **55** had no toxicity. In addition to the sarcophytonolide H series, we next evaluated the biological activity of the synthetic sarcophytonolide J (**69**) and its synthetic intermediates. The synthetic sarcophytonolide J (**69**), the triene **76**, and the hydroxyester **74** were antifouling active with EC₅₀ values of 0.95–2.36 µg/mL without regard to difference of the molecular framework. Interestingly, alcohol **81** also showed the antifoulant activity (EC₅₀ = 1.74 µg/mL) in contrast to the allylic alcohol **55** in the sarcophytonolide H series. In the sarcophytonolide J series, only compound **69** displayed the weak toxicity with a LC₅₀ value of 34.5 µg/mL and other compounds **76**, **74**, and **81** were non-toxic. These obtained results of the biological activity assessment shown in Table 4 denote that the triene **76**, which exhibited the strongest antifouling activity and no toxicity, is a promising candidate for the creation of environmentally friendly antifouling agents.

Conclusion

Unified total synthesis of sarcophytonolides, cembranolide diterpenes isolated from the soft corals of genus Sarcophyton, was accomplished. In their synthetic routes, NaHMDS-mediated reaction of allylic bromide/sulfone in methylene series at the C14 position and SmI₂-mediated reaction of allylic bromide/aldehyde in acetoxymethyne series at the C14 position were utilized as the fragment couplings, respectively. In addition, the total synthesis features alkoxycarbonylallylation, macrolactonization, and transannular RCM. Because the chirality at the C8 position of sarcophytonolide C (1) was not determined, the C8 stereoisomers 1a and 1b were stereoselectively synthesized, which elucidated the absolute configuration of natural 1 to be that as drawn in 1a. Stereoselective total synthesis of sarcophytonolides E (2), F (3), G (4), and H (6) culminated in the absolute stereochemical determination of 2, 3, and 4 and confirmation of 6. Furthermore, total synthesis of the proposed structure 10 and the predicted structure 68 of isosarcophytonolide D revealed the correct structure of this natural product to be that in **68**. This stereochemical revision at the C14 position of isosarcophytonolide D and the stereostructural elucidation of sarcophytonolide C led us to the stereochemical prediction of sarcophytonolide J. Total synthesis of the predicted structure 69 of this natural product verified the correct structure of natural sarcophytonolide J. After completing the total synthesis of sarcophytonolides, we assayed the cytotoxicity of selected synthetic products against HL60 cells and found that 1b, 2, 3, 6, 32b, 30b, and 25b showed the cytotoxicity, while **1a** was inactive. Moreover, we conducted evaluation of the antifouling activity and toxicity of the synthetic sarcophytonolides H (6) and J (69) and their synthetic analogues against the cypris larvae of barnacle Balanus (Amphibalanus) amphitrite. The obtained findings suggest that 76, a synthetic intermediate of 69, is a good candidate for further developing environmentally benign antifouling compounds. Further synthetic study of other classes of cembranolide is currently underway.

Cell Growth-Inhibitory Activity. HL60 cells were cultured at 37 °C with 5% CO₂ in RPMI (Nissui, Tokyo, Japan) supplemented with 10% heat-inactivated fetal bovine serum (FBS; Sigma-Aldrich Co., St. Louis, MO), 100 units/mL penicillin, 100 µg/mL streptomycin, 0.25 µg/mL amphotericin, 300 µg/mL L-glutamine, and 2.25 mg/mL NaHCO₃. HL60 cells were seeded at 1×10^4 cells/well in 96-well plates (Iwaki, Tokyo, Japan). Various concentrations of the synthetic compounds were then added, and cells were incubated for 72 h. Cell proliferation was measured by the MTT assay.

Antifouling Activity and Toxicity. Adult barnacles of *Balanus (Amphibalanus) amphitrite* were collected at Mega fishing port (Himeji, Hyogo, Japan) and maintained in aquaria at 20 ± 1 °C by feeding with brine shrimp (*Artemia salina*) nauplii for one week. Cypris larvae of barnacle *Balanus (Amphibalanus) amphitrite* were obtained by larval culture in the laboratory according to the method reported by Nogata and co-workers.⁶² Obtained cypris larvae were aged for 2–3 days prior to use at 5 °C in the dark. The effects of the synthetic compounds on the barnacle cyprids settlement were tested using 24-well polystyrene plates (Corning, NY, USA) according to our previous report.⁶³ Each compound was dissolved in MeOH. If the compound did not dissolve in MeOH, it was dissolved in a small amount of DMSO. Aliquots of the solution were applied to wells of 24-well polystyrene plates (0.1, 0.3, 1.0, 3.0, 10, and 50 µg) and air-dried. DMSO alone showed no effects on larval settlement at the concentration used in this assay (0.2%). Approximately 10 cypris larvae were added to each well filled with filtered natural seawater (28 psu) at final volume of 1.0 mL. After the incubation at 25 °C in

the dark for 96 h, the number of larvae, which settled (including metamorphosed larvae), died, or did not settle, was counted under a microscope. Each level of the experiments was carried out with three wells and the assay was repeated three times. The assay was performed with CuSO₄ (0.01, 0.03, 0.1, 0.3, 1.0, 3.0, and 10 μ g) as a positive control. The assay without compound was performed as a control. The antifouling activity and toxicity were expressed as EC₅₀ and LC₅₀ values, respectively. The EC₅₀ and LC₅₀ values were calculated by probit analysis according to Nogata's report.⁶⁴ When probit analysis could not be applied to calculate the values, these were estimated by straight-line graphical interpolation.

- (61) The observed specific rotation of the synthetic product 4 was different from that of natural sarcophytonolide G. However, the absolute value of the specific rotation reported for the natural product is quite small. Therefore, we have concluded that natural sarcophytonolide G possesses the absolute stereochemistries at the C1 and C2 positions same as those of other sarcophytonolides and the absolute configuration of the natural product is that depicted in 4.
