Abstract Methods for the preparation of symmetrical and nonsymmetrical 2,7-disubstituted 9*H*-fluorene derivatives are described.

Key words fluorene, sulfonamide, microwave-assisted synthesis

Fluorene (1, Figure 1) represents a privileged structure that has found a wide variety of applications in synthetic, medicinal, and materials chemistry. The defined shape and electronics of 1 impart important functional properties on derivatives.¹ For example, C_2 -symmetric bis-sulfonamide **2** is an effective ligand in the rhodium-catalysed asymmetric transfer hydrogenation of ketones.² Bis-sulfonamides are also prevalent in many commercial screening libraries and have been identified as hit compounds on diverse protein targets including alanine racemase,³ cysteine protease,⁴ and 17β-HSD1.⁵ In addition, bis-sulfonamide **3** has been used in chemical biology as a novel DNA G quadruplex ligand showing further applications for this class of compound.⁶ For each of these examples the rigid scaffold of fluorene provides the requisite geometry for function, holding substituents in a specific position. Along with the structural properties imparted by the framework, the conjugated nature of the two aromatic rings and the acidic methylene protons dictate the properties of derivatives. For example, bis-sulfonylated fluorenes have found use in areas such as self-assembled monolayer arrays for molecular electronic devices,⁷ compounds with room-temperature phosphorescent emission properties,8 charge-transfer complexes,9 and merocyanine dyes.¹⁰ Therefore, new methods for the preparation of fluorene derivatives that allow access to alternative and more complex scaffolds will be of interest to the synthetic community.

A key feature of fluorene chemistry that directs many of the applications of this framework is the regiospecific electrophilic aromatic sulfonylation,^{7a} nitration,¹¹ and halogenation,¹² which leads to 2,7-disubstituted systems for further elaboration. Surprisingly, the majority of fluorene derivatives reported to have function within the literature are symmetrical, presumably due to their ease of synthesis, and we were unable to identify effective methods to prepare nonsymmetrical compounds despite the potential applications of these products. Within this paper we describe simple and effective methods for the preparation of monosulfonamides together with symmetrical and nonsymmetrical bis-sulfonamides from commercial fluorene building blocks and also provide preliminary data to show a method for the preparation of aniline- and amide-substituted fluorene monosulfonamides.

As part of our ongoing investigations in nuclear receptor chemistry,¹³ virtual screening identified the symmetrical bis-sulfonamide **9** as a potential hit compound which was D. H. Jones et al.

therefore physically required for biological evaluation. Bissulfonyl chloride 4 was prepared by a modified literature procedure^{7a} and isolated without the need for purification by chromatography (see the Supporting Information for full details).

To our surprise, an experimental procedure for the monosulfonylation of fluorene has not been detailed in the literature.¹⁴ Application of standard reaction conditions with careful control of stoichiometry led to the selective sulfonylation of fluorene, and subsequent chlorination gave monosulfonyl chloride 6 in 75% yield over two steps.

Thermal methods have been described for the preparation of sulfonamides from the corresponding sulfonyl chloride. Whilst these methods proved effective, an alternative microwave procedure was established which proved more convenient due to the short reaction times involved (typically <15 min, Table 1).

Heating bis-sulfonyl chloride **4** in the presence of two equivalents of aniline in a mixture of THF, NaOH (2 M), and acetone at 100 °C for 15 minutes provided the bis-sulfonamide 8 (Table 1, entry 1, 93%) after purification by column chromatography. This method proved effective for both primary (Table 1, entries 1-3) and secondary (Table 1, entry 4) anilines. Aliphatic amines were also shown to be efficient

amines along with aniline substrates (Table 1, entries 8-10).

Having prepared a series of symmetrical bis- and monosulfonamides we were eager to discover if we could also access nonsymmetrical derivatives. Attempts were made to use monosulfonamides 7 as precursors to nonsymmetrical bis-sulfonamides, however, standard sulfonylation conditions (HSO₃Cl, AcOH, 140 °C) proved incompatible with the existing sulfonamide functionality, leading to intractable mixtures of products.

Recent work has shown that aryl sulfonamides can be accessed in a two-step one-pot procedure through a palladium-catalysed sulfination followed by reaction of the aryl sulfinate intermediate with an amine in the presence of Nbromosuccinimide (NBS).¹⁵ With this in mind, we envisaged nonsymmetrical bis-sulfonamides could be accessed by the route outlined in Scheme 1.

substrates for the transformation (Table 1, entries 5–7) and suggest this should be an effective and general method for the preparation of this class of compound. Reaction of monosulfonyl chloride 6 with one equivalent of amine gave the corresponding monosulfonamides in good yields. The reaction was found to be tolerant of primary and secondary

Conversion of 2-bromofluorene **18** into the sulfonyl chloride **19** proceeded smoothly under standard reaction conditions (80%, two steps), which was treated with *p*-toluidine (1 equiv) to give the corresponding sulfonamide **20** (63%). Reaction of this substrate with morpholine under the conditions described by Shavnya et al.¹⁵ gave the corresponding sulfonamide **21** in 77% yield. Unfortunately, complex mixtures of products were observed when performing this protocol using aniline or primary amine starting materials. The fluorene scaffold can readily undergo both oxidation and deprotonation which we believe to be the origin of the multiple products observed when using alternative amines within this protocol.

We also examined alternative palladium-catalysed coupling processes for the introduction of additional functional groups of relevance to catalysis, medicinal chemistry, and materials chemistry (Scheme 2). Treatment of bromo sulfonamide **20** with morpholine in the presence of RuPhosPd under microwave irradiation at 120 °C for 30 minutes provided the Buchwald–Hartwig coupling product **22** in 72% isolated yield after purification by column chromatography.¹⁶ We were also able to directly access amide derivatives of **20** by microwave irradiation at 90 °C for 30 minutes in the presence of morpholine, Pd(OAc)₂, Xantphos as a supporting ligand, $Mo(CO)_6$, and DMAP, providing **23** in 76% isolated yield.¹⁷ These initial examples suggest that **20** should be an effective substrate for a variety of palladium-catalysed coupling procedures, further adding to the potential diversity and subsequent application of the products.

It is established that aryl iodides can be beneficial in palladium-catalysed transformations due to an increased rate of oxidative addition. We envisaged that the scope of the sulfonamide forming reaction could be improved through the use of aryl iodide substrate **24** (Scheme 3). Sulfonyl chloride **25** was prepared using standard conditions in an excellent yield over two steps (88%), without the need for chromatographic purification. The intermediate sulfonyl chloride **25** was sensitive to heating in the presence of a base, but a modified procedure employing two equivalents of amine and stirring at room temperature overnight overcame this problem, giving sulfonamides **26** and **27** in good yields (see Supporting Information for full details).

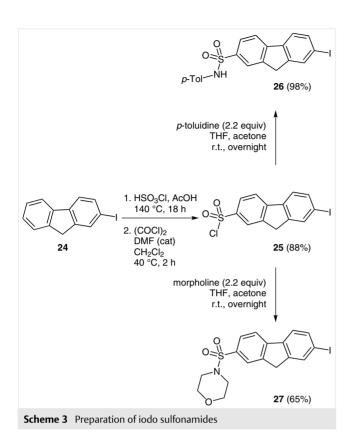

Sulfonamide **26** was reacted with morpholine under the conditions described by Shavnya et al.,¹⁵ however, a complex mixture of products was observed by LC–MS. A modest yield (48%) of **21** was achieved by using five equivalents of $K_2S_2O_5$, however, despite extensive exploration of reaction

conditions, a number of unidentified products predominated when using primary amines or anilines in this reaction. Alternative reported methods for the preparation of aryl sulfonamides from aryl halides were applied to sulfonamides **26** and **27**, however, in each case multiple products were observed.¹⁸

A nonelegant, transition-metal free solution to the preparation of nonsymmetrical bis-sulfonamides was found by treating bis-sulfonyl chloride **4** with one equivalent of *p*-toluidine under basic reaction conditions, giving

sulfonamide **28** in 15% yield after purification by column chromatography (Scheme 4). Subsequent reaction with oxalyl chloride gave sulfonyl chloride **29** which was then reacted with ethanolamine or 3-hydroxypropylamine to give the nonsymmetrical bis-sulfonamides **30** (95%) and **31** (43%), respectively. Of the methods examined this provided the most convenient process to access arrays of nonsymmetrical bis-sulfonamide targets in a reliable, time-efficient, and cost-effective manner.

In summary, we have described methods for the preparation of symmetrical and nonsymmetrical fluorene sulfonamide derivatives. Mono- and symmetrical bis-sulfonamides can be readily accessed through the microwave irradiation of the corresponding sulfonyl chloride in the presence of an amine, allowing access to the products in short reaction times. Nonsymmetrical bis-sulfonamides can be prepared in lower yields through the monofunctionalisation of bis-sulfonvl chloride **4**. followed by purification. reaction with oxalyl chloride, and then treatment with a second amine. Application of a palladium-catalysed sulfonvlation process also provides access to selected nonsymmetrical bis-sulfonamides but this transformation proved dependent on the structure of the amine nucleophile. Aniline and amide derivatives of the fluorene scaffold can also be prepared using transition-metal-catalysed coupling processes, adding to the structural diversity accessible through this methodology. Given the significant number of applications known for symmetrical fluorene derivatives in diverse areas including asymmetric catalysis, medicinal chemistry, and materials science it is expected that this work will provide the impetus for further discovery in the application of the fluorene skeleton.

(19) General Procedure for the Microwave-Assisted Formation of Sulfonamides

9H-Fluorene-2,7-disulfonyl dichloride (4, 100 mg, 0.28 mmol), acetone (1.52 mL), THF (0.28 mL), amine (0.56 mmol), and 2 M NaOH (aq, 0.32 mL) were added to a 5 mL microwave vial equipped with a magnetic stirrer bar. The mixture was heated in a Biotage Initiator at 100 °C for 15 min and allowed to cool to r.t. CH₂Cl₂ (10 mL) was added, and the mixture washed with water (10 mL), sat. Na2CO3 solution (10 mL), 2 M HCl (aq) solution (10 mL), and brine (10 mL). The organic extract was dried over MgSO₄, filtered, and concentrated under reduced pressure to give the crude product.

N,N-Diisopropyl-9H-fluorene-2,7-disulfonamide (13)

Prepared by the General Procedure, using isopropylamine (0.05 mL 0.58 mmol). Purified by column chromatography on silica (PE-EtOAc = 2:1, followed by 1:1) to give 13 as a yellow-orange solid (80 mg, 71%); mp 194-195 °C. IR (ATR): 3054, 2990, 1456, 1403, 1304, 1235, 1181, 1103 cm⁻¹. ¹H NMR (400 MHz, DMSO d_6): δ = 8.21 (2H, d, J = 8.1 Hz), 8.06 (2 H, d, J = 0.8 Hz), 7.89 (2 H, dd, I = 8.1, 1.5 Hz), 7.61 (2 H, d, I = 7.2 Hz), 4.18 (2 H, s), 3.22-3.35 (2 H, m), 0.96 (12 H, d, J = 6.5 Hz). ¹³C NMR (101 MHz, DMSO- d_6): δ = 144.7 (C_q), 143.0 (C_q), 141.1 (C_q), 125.5 (CH), 123.4 (CH), 121.5 (CH), 45.2 (CH), 36.7 (CH₂), 23.2 (CH₃). LC-MS: $m/z = 407.1 [M - 1]^+$. HRMS: m/z calcd for $C_{19}H_{23}O_4N_2S_2$: 407.1105; found: 407.1107.

Palladium-Catalysed Procedures

7-(Morpholinosulfonyl)-N-(p-tolyl)-9H-fluorene-2-sulfonamide (21)

A microwave vial was charged with 20 (30.0 mg, 0.062 mmol), K₂S₂O₅ (33.0 mg, 0.148 mmol), TBAB (26.3 mg, 0.082 mmol), NaO₂CH (12.0 mg, 0.176 mmol), Pd(OAc)₂ (1.0 mg, 5 mol%), Ph₃P (3.0 mg, 0.013 mmol), 1,10-phenanthroline (2.0 mg, 0.011 mmol), and DMSO (0.2 mL). The mixture was degassed by bubbling nitrogen through the solvent for 10 min, and then heated under argon at 70 °C for 3 h. Following cooling to r.t., a solution of morpholine (12.6 mg, 0.145 mmol) in anhydrous THF (1.0 mL) was added, and the mixture cooled to 0 °C. A solution of NBS (25.8 mg, 0.145 mmol) in THF (1.0 mL) was added dropwise and the mixture left to warm to r.t. over 1 h. Water (10 mL) was added, and the mixture extracted with EtOAc (3 × 10 mL). The organics were combined and washed with water (20 mL), brine (20 mL), dried over MgSO₄, filtered, and concentrated under reduced pressure to give the crude product, which was purified by column chromatography (PE-EtOAc = 1:1) to give 21 as a yellow solid (27 mg, 77%). ¹H NMR (400 MHz, acetone- d_6): δ = 8.87 (1 H, s), 8.19 (1 H, d, J = 8.0 Hz), 8.11 (1 H, d, J = 8.4 Hz), 8.01-8.06 (2 H, m), 7.81-7.88 (2 H, m), 7.11 (2 H, d, J = 8.4 Hz), 7.04 (2 H, d, J = 8.4 Hz), 4.14 (2 H, s), 3.62-3.72 (4 H, m), 2.93-3.03 (4 H, m), 2.21 (3 H, s). ¹³C NMR (101 MHz, acetone- d_6): δ = 146.2 (C_q), 145.9 (C_q), 145.2 (C_q), 144.8 (C_q), 140.5 (C_q), 136.1 (Cq), 135.7 (Cq), 135.3 (Cq), 130.5 (CH), 128.0 (CH), 127.3 (CH), 125.8 (CH), 125.1 (CH), 122.5 (CH), 122.3 (CH), 122.2 (CH), 66.7 (CH₂), 47.1 (CH₂), 37.7 (CH₂), 20.7 (CH₃). LC-MS m/z = 483.2 $[M - 1]^+$. HRMS: m/z calcd for $C_{25}H_{25}N_2O_5S_2$: 485.1199; found: 485.1189

7-Morpholino-N-(p-tolyl)-9H-fluorene-2-sulfonamide (22) A mixture of RuPhos palladacycle (7 mg, 0.05 equiv), RuPhos (5 mg, 0.05 equiv), NaOt-Bu (29 mg, 0.30 mmol), 7-bromo-N-(ptolyl)-9H-fluorene-2-sulfonamide (83 mg, 0.20 mmol), and morpholine (0.021 mL, 0.24 mmol) in 1,4-dioxane (0.50 mL) was sealed and heated in a Biotage Initiator at 120 °C for 30 min. After cooling, the sample was passed through a plug of Celite using MeOH (10.0 mL), then concentrated under reduced presD. H. Jones et al.

sure to give the crude product, which was purified by column chromatography (PE–EtOAc = 1:1) to give **21** (59 mg, 72%) as a yellow solid; mp 170 °C (decomp.); IR (ATR): 2922, 1612, 1512, 1451, 1419, 1243, 1189, 1111 cm⁻¹. ¹H NMR (400 MHz, CDCl₃): δ = 7.82 (1 H, d, *J* = 1.2 Hz), 7.70 (1 H, dd, *J* = 8.0, 0.8 Hz), 7.67 (1 H, d, *J* = 8.8 Hz), 7.64 (1 H, d, *J* = 8.4 Hz), 7.10 (1 H, d, *J* = 2.0 Hz), 6.99–7.04 (2 H, m), 6.92–6.98 (3 H, m), 6.41 (1 H, s), 3.86–3.92 (4 H, m), 3.83 (2 H, s), 3.20–3.28 (4 H, m), 2.26 (3 H, s). ¹³C NMR (101 MHz, CDCl₃): δ = 152.1 (C_q), 146.8 (C_q), 146.2 (C_q), 143.1 (C_q), 135.6 (C_q), 135.4 (C_q), 134.0 (C_q), 133.3 (C_q), 130.0 (CH), 126.7 (CH), 123.8 (CH), 122.7 (CH), 121.8 (CH), 118.9 (CH), 115.2 (CH), 112.1 (CH), 67.0 (CH₂), 49.5 (CH₂), 37.1 (CH₂), 21.0 (CH₃).
