

# Ruthenaphosphaalkenyls: Synthesis, Structures, and Their Conversion to $\eta^2$ -Phosphaalkene Complexes

Victoria K. Greenacre,<sup>†</sup> Nicola Trathen,<sup>†</sup> and Ian R. Crossley\*

Department of Chemistry, University of Sussex, Falmer, Brighton BN1 9QJ, U.K.

**S** Supporting Information

**ABSTRACT:** The ruthenaphosphaalkenyls  $[\text{Ru}\{\text{P}=\text{CH}(\text{SiMe}_2\text{R})\}\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  ( $\text{R} = \text{Me}, \text{Ph}, \text{Tol}$ ) have been prepared in good yield by the facile hydorruthenation of the respective phosphaalkynes,  $\text{RMe}_2\text{SiC}\equiv\text{P}$ , with  $[\text{RuHCl}(\text{CO})(\text{PPh}_3)_3]$ ; all three compounds have been structurally characterized in the solid state. Complemented by DFT studies of these, and the precedent  $[\text{Ru}\{\text{P}=\text{CH}(\text{tBu})\}\text{Cl}(\text{CO})(\text{PPh}_3)_2]$ , the phosphaalkenyl moieties have been established unequivocally to behave as one-electron donors to the coordinately unsaturated, 15-electron “ $\text{RuCl}(\text{CO})(\text{PPh}_3)_2$ ” fragment, corroborating an earlier demonstration of nucleophilic character at phosphorus within the *tert*-butyl system. Notwithstanding, the ruthenaphosphaalkenyls are shown to react with the nucleophiles  $\text{Lipz}'$  ( $\text{pz}' = \text{pz}, \text{pz}^*, \text{pz}^{\text{H,CF}_3}, \text{pz}^{\text{Me,CF}_3}$ ) to afford the  $\eta^1, \eta^2$ -chelated pyrazolylphosphaalkene complexes  $[\text{Ru}\{\eta^1\text{-N:N-P}, \text{C-P}(\text{pz}')=\text{CH}(\text{R})\}\text{Cl}(\text{CO})(\text{PPh}_3)_2]$ , which feature a three-membered metallacyclic ( $\text{Ru-C-P}$ ) core. The nature of these novel compounds is discussed, alongside preliminary insight into the process by which they are formed.

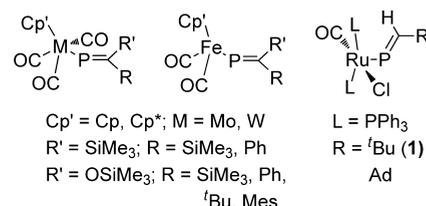

## INTRODUCTION

The chemistry of low-coordinate phosphacarbons has been an active area of research for over four decades,<sup>1</sup> and continues to be a topic of widespread interest.<sup>2</sup> Amidst this constantly developing field, phosphaalkenes ( $\text{RP}=\text{CR}'\text{R}''$ ) have long held particular importance, being among the earliest phosphacarbons to be studied in detail.<sup>3</sup> In an organometallic context, while both the  $\eta^1$ - and  $\eta^2$ -coordination complexes of phosphaalkenes have been studied,<sup>4</sup> albeit less extensively so for the latter case, a more prevalent interest has surrounded the metallaphosphaalkenes ( $\text{A-E}$ , Chart 1) in which at least one substituent on the “ $\text{P}=\text{C}$ ” moiety is replaced by either a transition metal fragment or main group metal.<sup>5</sup>

With the exception of those of type E, all possible metallaphosphaalkene motifs have been realized, albeit that work has been overwhelmingly focused on the *P*-metalla- (type A) and *C*-metalla- (type B) systems. These constitute intriguing extensions of the phosphacarbon paradigm “*the carbon copy*” in an organometallic context, particularly with respect to *P*-

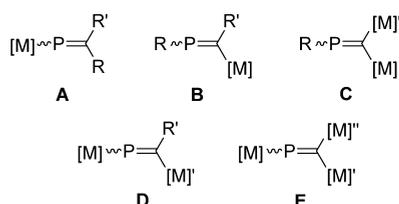

metallaphosphaalkenyls (type A). The first such compound,  $[\text{CpFe}(\text{CO})_2\{\text{P}=\text{C}(\text{SiMe}_3)\}^t\text{Bu}]$ , described in 1985,<sup>6</sup> was obtained through an extension of Becker’s methodology, via the interaction of  $^t\text{BuC}(\text{O})\text{Cl}$  with the bis(trimethylsilyl)-phosphide complex  $[\text{CpFe}(\text{CO})_2\text{P}(\text{SiMe}_3)_2]$ .<sup>7</sup> Subsequently, a range of such compounds was similarly obtained (Chart 2).<sup>8</sup>

## Chart 2. Representative *P*-Metallaphosphaalkenyls

Other prevalent synthetic routes have included (i) metathesis of *P*-halogenophosphaalkenes with carbonylmetallates,<sup>9</sup> (ii) metathesis of *P*-silylphosphaalkenes with transition metal halides ( $\text{L}_n\text{MX}$ ),<sup>10</sup> and (iii) oxidative addition of *P*-functionalized ( $\text{Cp}^*$ , Cl) phosphaalkenes to low-valent metal fragments ( $\text{M}(\text{NCMe})_3(\text{CO})_3$ , where  $\text{M} = \text{Cr}, \text{Mo}, \text{W}$ ; “ $\text{Fe}(\text{CO})_5$ ”;  $\text{Ni}(\text{PR}_3)_2(\text{cod})$ ;  $\text{Pt}(\text{PPh}_3)_2(\text{C}_2\text{H}_4)$ ).<sup>11</sup> The reduction of phosphaalkynes within the coordination sphere of a transition

**Received:** November 30, 2014

metal has also found some utility to this end, albeit typically accompanied by oligomerization of phosphalkyne units.<sup>12</sup> Notably, however, in 1996 Hill and Jones described the facile, stoichiometric reduction of  $t\text{BuC}\equiv\text{P}$  by the ruthenium hydride complex  $[\text{RuHCl}(\text{CO})(\text{PPh}_3)_3]$ .<sup>13</sup> Akin to the established alkyne hydroruthenation protocols,<sup>14</sup> this afforded the ruthenaphosphaalkenyl  $[\text{Ru}(\text{P}=\text{CH}^t\text{Bu})\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  (**1**),<sup>13,15</sup> the thiocarbonyl analogue of which was similarly obtained, alongside analogues derived from  $\text{AdC}\equiv\text{P}$ .<sup>15</sup> Jones subsequently reported the successful double hydroruthenation of his bicyclo[2.2.2]octane-1,4-diphosphaalkyne,<sup>16</sup> though Hill's attempts to prepare an osmium analogue of **1** were thwarted by its facile incorporation of a second equivalent of  $t\text{BuC}\equiv\text{P}$  to afford a phosphalkenyl-phosphaalkene complex.<sup>17</sup>

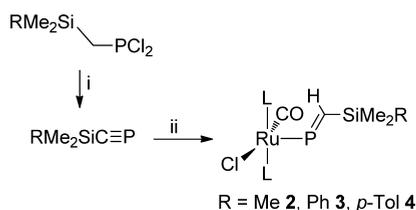

Compound **1** is notable in featuring both a relatively unencumbered phosphalkenyl moiety (cf. the classical use of sterically demanding and/or  $\pi$ -donative substituents to confer stability) and apparent unsaturation at the metal center. For early transition metals, such unsaturation results in additional donation of the phosphalkenyl lone pair to the metal, viz. adoption of a three-electron phosphavinylidene ligation mode,<sup>9a,c,18</sup> resulting in electrophilicity of the phosphorus center. However, while structural data for **1** have not been described, the demonstration of nucleophilicity at phosphorus,<sup>19</sup> in a series of 1,2 additions across the P–Ru linkage, was deemed characteristic of a “bent” one-electron P-phosphaalkenyl ligand<sup>15</sup> within an overall 16-electron complex; the latter was somewhat supported by isolation of 18-electron complexes upon addition of a series of two-electron donors (CO, CNR), though a significant trans influence was noted for the phosphalkenyl.<sup>13,15</sup>

Notwithstanding, while investigating an analogue of **1**, viz.  $[\text{Ru}\{\text{P}=\text{CH}(\text{SiMe}_3)\}\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  (**2**), we noted unexpected ambiphilic behavior. Thus, as we have recently communicated,<sup>20</sup> while **2** readily undergoes 1,2 additions consistent with a nucleophilic phosphorus center, its interaction with the pyrazolates  $[\text{pz}'^-]$  ( $\text{pz}' = \text{pz}, \text{pz}^*$ ) also results in functionalization at phosphorus. Herein, we describe further investigation of this unusual behavior, including a structural study of the parent phosphalkenyls.

## RESULTS AND DISCUSSION

**Ruthenaphosphaalkenyl Complexes.** In a manner similar to that previously described for **1**,<sup>13</sup> the novel ruthenaphosphaalkenyls  $[\text{Ru}\{\text{P}=\text{CH}(\text{SiMe}_2\text{R})\}\text{Cl}(\text{CO})(\text{PPh}_3)_2]$  ( $\text{R} = \text{Me}$  **2**,  $\text{Ph}$  **3**,  $p\text{-Tol}$  **4**) were obtained from the reaction of  $[\text{RuHCl}(\text{CO})(\text{PPh}_3)_3]$  with excess of the respective phosphalkyne  $\text{RMe}_2\text{SiC}\equiv\text{P}$ <sup>21,22</sup> (Scheme 1), the latter generated as toluene solutions by the double dehydrochlorination of  $\text{RMe}_2\text{SiCH}_2\text{PCL}_2$ .<sup>23</sup>

### Scheme 1. Synthesis of Phosphaalkenyls 2–4<sup>a</sup>

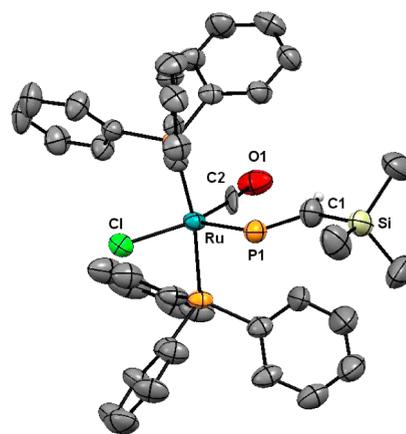

<sup>a</sup>Reagents and conditions: (i)  $2\text{AgOTf}$ ,  $2\text{DABCO}$ , toluene; (ii)  $[\text{RuHCl}(\text{CO})(\text{PPh}_3)_3]$ ,  $\text{CH}_2\text{Cl}_2$  ( $\text{L} = \text{PPh}_3$ ).

The identities of **2–4** follow convincingly from analytical and spectroscopic data. Thus, the  $^{31}\text{P}$  NMR spectra exhibit doublet-based resonances associated with the retained  $\text{PPh}_3$  ligands ( $\delta_{\text{P}}$  34.6, **2**; 33.7, **3**; 33.7, **4**), with mutual coupling (8 Hz) to heavily deshielded resonances ( $\delta_{\text{P}}$  548.5,  $J_{\text{PH}} = 21$  Hz, **2**; 553.8,  $J_{\text{PH}} = 20$  Hz, **3**; 552.6,  $J_{\text{PH}} = 20$  Hz, **4**) that lie in a region characteristic of P-metallaphosphaalkenyls.<sup>8–12</sup> The latter collapse to triplets in the  $^{31}\text{P}\{^1\text{H}\}$  NMR spectra, consistent with loss of the scalar interaction to their respective vinylic proton, the resonances for which are assigned on the basis of  $^{31}\text{P}\text{--}^1\text{H}$  HMBC spectra ( $\delta_{\text{H}}$  7.28, **2**; 7.40, **3**; 7.41, **4**), alongside their correlation to the carbon ( $\delta_{\text{C}}$  168.0, **2**; 163.7, **3**; 165.2, **4**) and silicon ( $\delta_{\text{Si}}$   $-9.4$ , **2**;  $-14.3$ , **3**;  $-14.4$ , **4**) centers of the phosphalkenyl moiety. Retention of the carbonyl ligand is in each case confirmed by infrared data ( $\nu_{\text{CO}} = 1920$   $\text{cm}^{-1}$ , **2**;  $1938$   $\text{cm}^{-1}$ , **3**;  $1936$   $\text{cm}^{-1}$ , **4**), the associated  $^{13}\text{C}\{^1\text{H}\}$  NMR resonances of which ( $\delta_{\text{C}}$  203.0, **2**; 201.9, **3**; 202.5, **4**) are also observed.

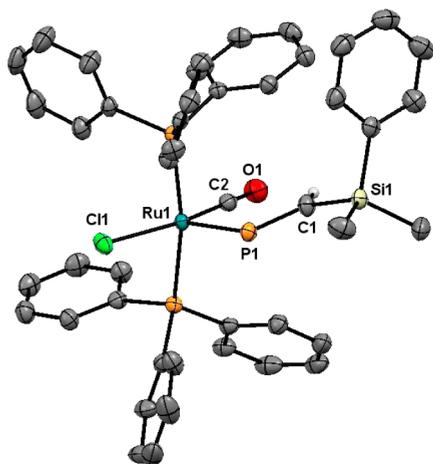

It is noteworthy that the low-coordinate phosphorus centers of **2–4** are significantly more deshielded than that of **1** ( $\delta_{\text{P}}$  450.4).<sup>13</sup> We attribute this to the differing substituent at the adjacent alkenic carbon ( $\text{SiR}_3$  vs  $^t\text{Bu}$ ), given the similar disparity noted between the parent phosphalkynes  $\text{RC}\equiv\text{P}$  ( $\delta_{\text{P}}$  for  $\text{R} = \text{Ph}$ ,  $-67$ ;  $\text{SiMe}_3$ ,  $98.7$ ;  $\text{SiMe}_2\text{Ph}$ ,  $102.7$ ;  $\text{SiMe}_2\text{Tol}$ ,  $103.3$ ). However, one cannot immediately discount the possibility of differing coordination modes; indeed, though compound **1** was concluded to involve a one-electron phosphalkenyl ligand (*vide supra*),<sup>15</sup> the lack of structural verification, alongside a noted strong trans influence, do not fully preclude the possibility of some phosphavinylidene character (*vide infra*).

From a structural stand-point, the silyl derivatives **2–4** (Figures 1–3, Table 1) would seem consistent with the

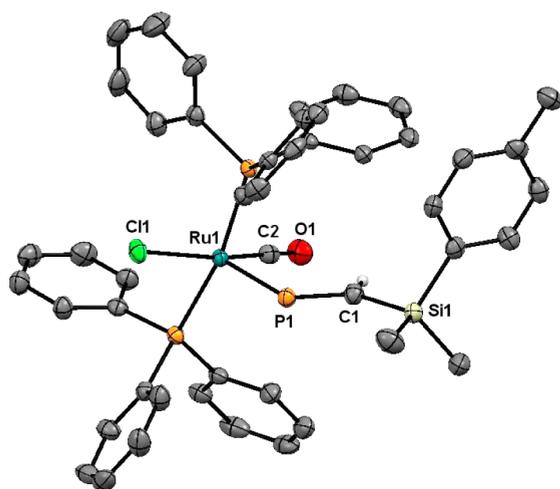

**Figure 1.** Molecular structure of **2** in molecules of the  $\text{Et}_2\text{O}$  solvate; 50% thermal ellipsoids, hydrogen atoms omitted for clarity.

phosphaalkenyl being engaged in one-electron ligation to the metal. Thus, a distinctly “bent” geometry is noted for the phosphalkenyl moiety ( $\angle\text{Ru-P-C} = 121.3(2)\text{--}124.4(4)^\circ$ ;  $\angle\text{P-C-Si} = 122.5(7)\text{--}125.6(2)^\circ$ ) with no evidence for linearization. The Ru–P linkages are relatively short ( $d_{\text{RuP}} = 2.226(2)\text{--}2.2503(10)$  Å) in comparison to ruthenium-phosphido complexes ( $2.382\text{--}2.512$  Å<sup>24</sup>), those of the  $\eta^1$ -phosphaalkene complexes  $[\text{Ru}\{\eta^1\text{-P}(\text{E})=\text{CH}(\text{R})\}\text{Cl}_2(\text{CO})(\text{PPh}_3)_2]$  ( $\text{R} = ^t\text{Bu}$ ,  $\text{E} = \text{Au}(\text{PPh}_3)$ ,<sup>19b</sup>  $\text{HgFc}$ ;<sup>19c</sup>  $\text{R} = \text{SiMe}_3$ ,  $\text{E} = \text{HgPh}$ ;<sup>20</sup>  $d_{\text{Ru-P}} = 2.256(2)\text{--}2.296(2)$  Å) and that reported for Hill's 18-electron phosphalkenyl  $[\text{Ru}\{\text{P}=\text{CH}^t\text{Bu}\}(\text{O}_2\text{CH})\text{--}$

<sup>a</sup>Bond distances (Å) and angles (deg) with estimated standard deviations in parentheses. <sup>b</sup>The structure for **2** suffers from some disorder around the carbonyl carbon; associated parameters should be interpreted with caution.

(CO)(PPh<sub>3</sub>)<sub>2</sub>] (2.295(2) Å).<sup>15</sup> They are also shorter than those reported by Peters for [Ru{κ<sup>4</sup>-Si(C<sub>6</sub>H<sub>4</sub>PPh<sub>2</sub>)<sub>3</sub>}{PR<sub>2</sub>}] (R = Ph, 2.2700(3) Å; <sup>i</sup>Pr, 2.2592(4) Å), which exhibit appreciable Ru=P double bond character, as evidenced by planarity of the Ru–PR<sub>2</sub> unit.<sup>25</sup> However, the distances of **2–4** do compare well with the Ru←PR<sub>3</sub> distances recorded for other square-based pyramidal ruthenium(II) complexes (2.16–2.47 Å),<sup>24</sup> while the

P=C bonds ( $d_{P=C}$  = 1.655(2)–1.660(11) Å) are comparable to those of the η<sup>1</sup>-phosphaalkene complexes (1.662(5)–1.69(2) Å), Hill's 18-electron system (1.640(8) Å), and phosphaalkenyls more generally (1.65–1.75 Å).<sup>24</sup> It is thus fair to conclude a lack of any higher-order character for the Ru–P linkage; this is also borne out by DFT studies (*vide infra*).

The molecular geometries are otherwise largely unremarkable. The interligand angles about ruthenium ( $\angle$ Cl–Ru–CO = 162.68(8)–163.56(12)°;  $\angle$ P<sub>PR<sub>3</sub></sub>–Ru–P<sub>PR<sub>3</sub></sub> 166.62(2)–167.18(7)°) are typical of square-based pyramidal Ru(II), and C≡O distances are similarly consistent. The phosphaalkenyl moieties are in each case essentially coplanar with the carbonyl ligand ( $\phi$  = 8.2(6)°, **2**; 17.93(10)°, **3**; 17.89(17)°, **4**), with which they also adopt a *cis* conformation, as was observed for [Ru{P=CH<sup>t</sup>Bu}(O<sub>2</sub>CH)(CO)(PPh<sub>3</sub>)<sub>2</sub>]<sup>15</sup> and has been previously noted for analogous ruthenium vinyl complexes.<sup>24,26</sup> In the latter cases, this has been attributed to achieving optimal  $d_{\pi} \rightarrow \pi^*$  retro-donation to both the carbonyl and alkenyl ligands, coupled with a consequentially significant barrier to rotation about the Ru–C<sub>alkene</sub> linkage, and a marginal thermodynamic preference for the *cis* rather than *trans* arrangement (ca. 2 kcal mol<sup>−1</sup>) of the two ligands.<sup>27</sup> A comparable situation would seem likely for the phosphaalkenyl analogues.

**DFT Studies.** The ground-state geometries of complexes **1–4** were optimized using DFT methods, commencing either from the solid-state data (**2–4**) or from hypothetical models (**1** and **2**); in each case, geometries were obtained that compare well with the experimental (solid-state) structures of **2–4** (see Supporting Information).

The calculated IR data ( $\nu_{CO}$ ) and <sup>31</sup>P NMR isotropic shielding tensors (lanl2dz on Ru; 6-31G\*\* all other atoms) of **1–4**, show moderate agreement with experimental data, but do closely reflect the observed trends (Table 2). In particular, the

<sup>a</sup>B3LYP. <sup>b</sup>lanl2dz on Ru; 6-31G\*\* on all other atoms. <sup>c</sup>Frequency scaling factor of 0.961 applied. <sup>d</sup>CH<sub>2</sub>Cl<sub>2</sub> solutions. <sup>e</sup>Using GIAO method, referenced against H<sub>3</sub>PO<sub>4</sub> at the same level of theory. <sup>f</sup>As CD<sub>2</sub>Cl<sub>2</sub> solutions.

computed <sup>31</sup>P NMR shifts for the P<sub>alkenyl</sub> centers indicate appreciably greater shielding within **1** ( $\Delta\delta_P \approx -100$  ppm w.r.t. **2**) compared with the silyl systems; this substantiates the notion that this feature is of purely electronic origin (i.e., <sup>t</sup>Bu vs SiMe<sub>2</sub>R) rather than being the result of any geometric distinctiveness. Indeed, attempts to optimize the geometry of **1** using a phosphavinylidene model resulted in relaxation to the phosphaalkenyl motif (Figure 4), which exhibits no evidence for involvement of the lone pair in metal binding.

For all four complexes the frontier orbitals are dominated by the metal and phosphaalkenyl fragments (Figure 5). Thus, for **2–4**, the HOMO involves appreciable bonding overlap between ruthenium and the phosphaalkenyl σ-framework, and also incorporates the phosphorus lone pair. A somewhat lesser

**Figure 4.** Optimized core geometry of **1**, with phenyl rings and ancillary hydrogen atoms omitted for clarity. Selected bond distances (Å) and angles (deg): Ru–P 2.318, P=C 1.680, Ru–CO 1.846, C≡O 1.166, Cl–Ru–C 159.02, Ru–P–C 118.05 P=C–C 126.54.

**Figure 5.** Representative frontier orbitals for compound **2**.

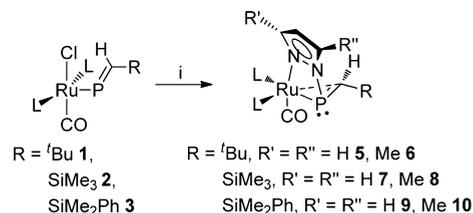

component of  $d_{\pi} \rightarrow \pi^*(\text{CO})$  retro-donation is also apparent. The HOMO–1, which lies essentially orthogonal to the HOMO (with respect to the metal  $d$  orbitals and alkenyl moiety) and around 0.1 eV lower in energy, is composed of out-of-phase mixing of the metal  $d_{\pi}$  orbital and phosphalkenyl  $\pi$ -system, and in the cases of **3** and **4** a small contribution from the arene  $\pi$ -orbitals. For **1**, the HOMO and HOMO–1 are reversed, though again close in energy (0.09 eV) and with the same general composition.

In all cases the LUMO is appreciably separated from the HOMO (3.76–3.87 eV), largely metal-based, and accessible to nucleophiles through the basal plane. Interestingly, for **2**–**4** the LUMO+1, which is only modestly higher in energy (ca. 0.6 eV), involves an appreciable contribution from the phosphalkenyl  $\pi^*$  orbital; the equivalent orbital of **1** is at LUMO+2, ca. 0.8 eV above the LUMO. This is significant, given that NBO calculations indicate an appreciable  $\delta^+$  character at the alkenyl phosphorus atom (0.55–0.76). Taken together, these features would seem to imply the possibility of at least some electrophilic character for this center, alongside the unequivocally established nucleophilicity associated with the accessible lone pair (HOMO). This has potential implications with respect to the noted ambiphilicity of these systems (*vide infra*).<sup>20</sup>

**Synthesis of  $\eta^2$ -Phosphaalkene Complexes.** The ruthenaphosphaalkenyls **1**–**3** all react readily, in THF solution, with single equivalents of the lithium pyrazolates Lipz' ( $\text{pz}' =$

$\text{pz}$ ,  $\text{pz}^*$ ) to afford in each case high yield of a single species (**5**–**10**, Scheme 2). As we have previously communicated,<sup>20</sup> the

**Scheme 2.** Reactions of **1**–**3** with Lipz' ( $\text{pz}' = \text{pz}$ ,  $\text{pz}^*$ )<sup>a</sup>

<sup>a</sup>Reagents and conditions: (i) Lipz' ( $\text{pz}' = \text{pz}$ ,  $\text{pz}^*$ ), THF, rt, 1 h. Comparable methodology is used to obtain **11**–**14** from Lipz<sup>CF<sub>3</sub></sup> and Lipz<sup>Me,CF<sub>3</sub></sup>.

connectivity of compounds **7** and **8** was established from X-ray diffraction data, which were readily reconciled with characteristic features of the multinuclear NMR spectra. Thus, while **5**, **6**, **9**, and **10** have yet to yield X-ray-quality crystals, their comparable nature is apparent from their spectroscopic signatures (Table 3). In all cases three (1:1:1) mutually coupling resonances are apparent in the <sup>31</sup>P{<sup>1</sup>H} NMR spectra, in a region (10–60 ppm) typically characteristic of saturated phosphorus centers, while the heavily deshielded phosphalkenyl resonance has been lost. Notwithstanding, retention of the <sup>t</sup>Bu (**5**, **6**) or SiMe<sub>2</sub>R (**7**–**10**) moieties is apparent from the <sup>1</sup>H NMR spectra (supported by <sup>1</sup>H–<sup>29</sup>Si correlation for **7**–**10**), the respective resonances integrating consistently against those in the aromatic region, which indicate retention of both PPh<sub>3</sub> ligands. Moreover, <sup>1</sup>H and <sup>13</sup>C NMR resonances associated with the P–CH unit are observed, identified on the basis of correlation experiments, albeit in significantly more shielded positions; the “P–CHR” unit can thus be concluded to be intact, albeit no longer phosphalkenyl in nature. Finally, retention of the carbonyl ligand is confirmed by both characteristic infrared and <sup>13</sup>C{<sup>1</sup>H} NMR data.

The precise nature of the three-membered (Ru–C–P) cyclic core of these compounds is a matter of intrigue. The crystallographic data<sup>20</sup> for **7** and **8** indicated significant pyramidalization about the C<sub>alkene</sub> center ( $\angle\text{P–C–H} = 112.8^\circ$ ,  $\angle\text{Si–C–H} = 112.8^\circ$ ,  $\angle\text{P–C–Si} = 116.7^\circ$ ) with concomitant lengthening of the P–C linkage (1.793(6) Å), superficially consistent with a ruthenaphosphirane geometry. Indeed, <sup>1</sup>H and <sup>13</sup>C NMR spectroscopic data would also seem to support such formalism, the “P–CH” moiety exhibiting shifts consistent with a saturated system (for **7**,  $\delta_{\text{H}} 1.59$ ,  $\delta_{\text{C}} 47.5$ ; for **8**,  $\delta_{\text{H}} 1.62$ ,  $\delta_{\text{C}} 44.9$ ). The C–H coupling magnitudes for the “P–CH” moiety ( $J_{\text{CH}} = 137$  Hz, **7**; 123 Hz, **8**) are, however, more ambiguous, being intermediate between those characteristic of “sp<sup>3</sup>” (cf. 125 Hz in CH<sub>4</sub>) and “sp<sup>2</sup>” (cf. 156 Hz in C<sub>2</sub>H<sub>4</sub>)<sup>28</sup> models; moreover, minimal perturbation of the P–C coupling magnitude ( $^1J_{\text{PC}} \approx 79$  Hz; cf.  $^1J_{\text{PC}} = 77$  Hz in **3**) is also superficially consistent with retention of appreciable “sp<sup>2</sup>” character. Intermediate character is also reflected in the fact the P–C linkage remains shorter than both a typical P(sp<sup>3</sup>)–C(sp<sup>3</sup>) single bond (1.855(19) Å)<sup>29</sup> and those of other known phosphiranes (1.8–1.9 Å).<sup>24</sup>

The spectroscopic data for all compounds **5**–**10** show a consistent trend, though it is again noted that replacement of silyl with *tert*-butyl results in significant deshielding of the “P–CH” unit (cf. **1** vs **2**–**4**). This is markedly more pronounced than for the parent phosphalkenyls, which may suggest a more

<sup>a</sup>NMR spectra recorded in CD<sub>2</sub>Cl<sub>2</sub> for compounds 5–10 inclusive; CDCl<sub>3</sub> for 11–14. <sup>b</sup>Referenced to 85% H<sub>3</sub>PO<sub>4</sub>. <sup>c</sup>Referenced to SiMe<sub>4</sub>. <sup>d</sup>Measured using coupled <sup>1</sup>H–<sup>13</sup>C HSQC spectra. <sup>e</sup>Recorded as solutions in CH<sub>2</sub>Cl<sub>2</sub>.

“alkene-like” character than for the silyl derivatives; however, the magnitude of <sup>1</sup>J<sub>CH</sub> in **6** (137 Hz) is comparable, while a slightly greater variation in <sup>1</sup>J<sub>PC</sub> coupling (67 Hz, **5**; 69 Hz, **6**) over the alkenyl (<sup>1</sup>J<sub>PC</sub> ≈ 59 Hz, **1**)<sup>13</sup> may reflect a marginal increase in s-character. Finally, infrared spectroscopic data for **5**–**10** indicate a significant reduction in the carbonyl stretching frequencies in comparison to the parent phosphaalkenyls. Indeed, while  $\nu_{CO}$  for the latter are entirely consistent with Ru(II) (*vide supra*; 1929 cm<sup>-1</sup> for **1**), those of **5**–**10** are more akin to the limited range of Ru(0) monocarbonyls reported to date (1910–1880 cm<sup>-1</sup>),<sup>30</sup> while the force constants for the C≡O bond are consistent with those derived from Ru(0) dicarbonyls.<sup>31</sup>

Taken together, these data suggest that compounds **5**–**10** are perhaps best described using the Dewar–Chatt–Duncanson model, and formulated as  $\eta^2$ -phosphaalkene complexes. Thus,  $d_{\pi \rightarrow \pi^* (P=C)}$  retro-donation can be considered a dominant contribution to metal–ligand binding (albeit potentially diminished in complexes **5** and **6**, a corollary of reduced acceptor character of *tert*-butyl compared with silyl), as was described by Cowley for [Ni{ $\eta^2$ -(Me<sub>3</sub>Si)<sub>2</sub>C=PCH(SiMe<sub>3</sub>)<sub>2</sub>}(PMe<sub>3</sub>)] ( $d_{P=C} = 1.773(8)$  Å),<sup>32</sup> which also exhibited a significantly low-frequency resonance for P<sub>alkene</sub> ( $\delta_P = 23$ ). More recently, Ionkin described a similar situation ( $\delta_P = 54$ ) for his chelated phosphaalkene complex (Chart 3),<sup>33</sup> the significant

Chart 3. A Chelated Ruthenium  $\eta^2$ -Phosphaalkene Complex

shift from the free ligand ( $\delta_P = 248$ ), which was mirrored in the <sup>13</sup>C data ( $\delta_C = 67$ , cf. 181 for the free ligand), being deemed consistent with an  $\eta^2$ -coordination mode. These data fit well with the trends noted herein.

A further notable feature in the spectroscopic data of **5**–**10** is the appreciable shielding of the P<sub>alkene</sub> center in the 1,3-dimethylpyrazole derivatives, compared with their pyrazole analogues, presumably reflecting the enhanced donor strength of pz\* over pz. This was verified by preparing the analogues **11**–**14**, which incorporate pz<sup>CF<sub>3</sub></sup> and pz<sup>Me,CF<sub>3</sub></sup> moieties.<sup>34</sup> The

spectroscopic data (Table 3) in each case reflect the anticipated trend in  $\delta_P$  for the P<sub>alkene</sub> center (pz\* < pz < pz<sup>Me,CF<sub>3</sub></sup> < pz<sup>CF<sub>3</sub></sup>), the more electron-withdrawing CF<sub>3</sub> moiety imparting appreciable deshielding. It is noteworthy that in each of **11**–**14** a single positional isomer is apparently formed with respect to the pyrazolyl substituents, the assignment of which is nontrivial in lieu of structural data. However, while the CF<sub>3</sub> moieties exhibit correlation to both P<sub>alkene</sub> and one of the PPh<sub>3</sub> ligands, only for the former is an appreciable coupling observed (<sup>4</sup>J<sub>PF</sub> ≈ 20 Hz), consistent with CF<sub>3</sub> being proximal to the P<sub>alkene</sub> center. This can be rationalized in terms of the steric demand of accommodating the bulkier CF<sub>3</sub> (cf. Me) between flanking PPh<sub>3</sub> units. Indeed, reacting **2** or **3** with Lipz<sup>(CF<sub>3</sub>)<sub>2</sub></sup>, for which this is unavoidable, fails to afford the fluorinated analogues of **8** and **10**, resulting instead in degradation of the ruthenaphosphaalkenyls; comparable results are noted with Lipz<sup>(<sup>t</sup>Bu)<sub>2</sub></sup>, thus negating the possibility of an electronic effect associated with the bis-trifluoromethyl system.

**DFT Studies.** The optimized ground-state geometries of **5** and **7** (Figure 6) both show good agreement with the solid-

Figure 6. Optimized geometries of **5** (left) and **7** (right), with hydrogen atoms and phenyl rings omitted for clarity.

state data for the latter.<sup>20</sup> There is only marginal variation in geometry about the P–CH moiety, **5** exhibiting a slightly wider P–C–R angle (119.24°, cf. 117.23° in **7**) and increased displacement of carbon from the metal center (2.244 Å, cf. 2.240 Å in **7**), while other parameters are comparable. This would seem to exclude significant variation in the extent of “alkene” character being responsible for the observed spectroscopic variations between silyl and <sup>t</sup>Bu systems. Indeed, though the calculated isotropic shielding tensors for **5** and **7** (<sup>31</sup>P, <sup>13</sup>C, and <sup>1</sup>H, see Table 4) are in less close agreement than for their parent phosphaalkenyls (*vide supra*), they do mirror the experimental trend. Thus, for the “P–CH” fragment, the phosphorus center of **5** resonates at a somewhat lower frequency than that of **7** ( $\Delta\delta_P = -13.6$ , cf.  $-19.9$  expt), while significant

<sup>a</sup>Lan12dz on Ru; 6-31G\*\* on all other atoms. <sup>b</sup>Data for the P–CH fragment, calculated using the GIAO method, referenced against H<sub>3</sub>PO<sub>4</sub> and Me<sub>4</sub>Si at the same level of theory. <sup>c</sup>B3LYP, frequency scaling factor of 0.961 applied.

deshielding is also apparent for both <sup>13</sup>C and <sup>1</sup>H nuclei ( $\Delta\delta_{\text{C}} = 31.4$ ,  $\Delta\delta_{\text{H}} = 1.25$ , cf. 34.0 and 1.22 expt). The calculated carbonyl stretching frequencies correlate well with the experimental data, the significant decrease from those of the parent phosphalkenyls being consistent with reduction of the metal (Ru(II)→Ru(0)), as previously inferred (*vide supra*).

**Mechanistic Considerations.** The mechanism by which compounds 5–14 form from the respective phosphalkenyls and Lipz' is the subject of ongoing experimental and computational studies; however, brief comment is warranted. Intuitively, one might anticipate nucleophilic attack at the ruthenium center, given its predominant contribution to the LUMO and accessibility through the basal plane. Indeed, complex 1 was shown to readily add donors (CO, CNR) at this site,<sup>15</sup> albeit that an apparently strong *trans* influence imparted significant lability. Moreover, the reaction of 1 with the carboxylate salts Na[O<sub>2</sub>CR] (R = H, Fc) was shown to afford [Ru{P=CH<sup>t</sup>Bu}(O<sub>2</sub>CH)(CO)(PPh<sub>3</sub>)<sub>2</sub>] via formal nucleophilic displacement of chloride,<sup>15</sup> presumably via an associative mechanism. It is also reasonable to consider that in the reaction of 1 or 2 with electrophilic species such as RHgCl, MeI or AuCl(L),<sup>15,19a,b,e,20</sup> the ensuing 1,2 addition across the Ru–P bond involves installation of a nucleophilic fragment (X<sup>-</sup>) at the vacant metal site, though whether this is concomitant with addition of the electrophilic fragment to phosphorus, or facilitated by it, has not been established.

However, one cannot arbitrarily dismiss the possibility of initial nucleophilic attack at the phosphorus center. While nucleophilicity at this site is characteristic of one-electron phosphalkenyls and has been well established for both 1<sup>15</sup> and 2,<sup>20</sup> NBO analysis (*vide supra*) has provided evidence of appreciable  $\delta+$  character. Moreover, as noted, the  $\pi^*$ <sub>(P=C)</sub> orbital is a significant component of the LUMO+1 (LUMO+2 in 1), which lies moderately close in energy to the LUMO ( $\Delta_{\text{E}} \approx 0.6$  eV), thus offering a viable competitive pathway. Notwithstanding, in the formation of 11–14, we have inferred the influence of sterics in directing the bulkier CF<sub>3</sub> substituent (cf. H, Me) to orient away from the metal center; we have also noted this in the reaction of 2 with Lipz<sup>tBu</sup>.<sup>35</sup> While not fully excluding the possibility of attack at phosphorus,<sup>36</sup> this outcome would necessarily follow from an associative addition to ruthenium, sterics likely precluding approach of the more encumbered ( $\alpha$ -CF<sub>3</sub> or <sup>t</sup>Bu) nitrogen center. Thus, while we are yet to reach a definitive conclusion, weight of evidence would currently suggest initial addition to the ruthenium center, presumably followed by elimination of LiCl. However, the process by which the putative pyrazolate complexes [Ru{P=CH(R)}(pz')(CO)(PPh<sub>3</sub>)<sub>2</sub>] subsequently convert to [Ru{ $\eta^1$ -N: $\eta^2$ -P,C-P(pz')=CH(SiMe<sub>3</sub>)}(CO)(PPh<sub>3</sub>)<sub>2</sub>] with concomitant reduction of the metal remains unclear.

## CONCLUDING REMARKS

We have described the synthesis of several ruthenaphosphaalkenyl complexes by the hydorruthenation of the silylphosphaalkynes RMe<sub>2</sub>SiC≡P (R = Me, Ph, *p*-Tol), and provided the first structural (X-ray and DFT) characterization of these intriguing compounds. The complexes are thus confirmed to adopt square-pyramidal geometry about ruthenium and comprise a formal one-electron phosphalkenyl ligand, as was previously inferred for [Ru{P=CH(<sup>t</sup>Bu)}Cl(CO)(PPh<sub>3</sub>)<sub>2</sub>] on the basis of reactivity studies. While that latter remains elusive to crystallographic study, DFT has provided adequate evidence to confirm a comparable geometry to its silyl counterparts.

All of the complexes are found to react with lithium pyrazolates, seemingly resulting in reduction of both the metal (Ru(II)→Ru(0)) and phosphalkenyl moiety. The resulting complexes exhibit a metallacyclic core (Ru–P–C) that might feasibly be described as a ruthenaphosphirane, the Ru–P bond of which is additionally bridged by the pyrazolyl group. However, spectroscopic and structural data are inconclusive, being equally consistent with the  $\eta^2$ -coordination of a phosphalkene, tethered by the pyrazolyl moiety, with a dominant bonding contribution from  $d_{\pi} \rightarrow \pi^*_{\text{P=C}}$  retro-donation. Indeed, on balance, we currently favor this description, based on the Dewar–Chatt–Duncanson model. Regardless of the correct formalism, the process by which these novel complexes are obtained is equally intriguing and remains to be firmly established. While it is not currently possible to fully discount the direct nucleophilic attack at phosphorus—which would imply true ambiphilic character for the phosphalkenyl ligand, for which some support is found—evidence would seem to favor initial addition of the pyrazolate to ruthenium. However, the full mechanistic features of this reaction remain to be established, and are the subject of ongoing investigations.

## EXPERIMENTAL SECTION

**General Methods.** All manipulations were performed under strict anaerobic conditions using standard Schlenk line and glovebox (MBraun) techniques, working under an atmosphere of dry argon or dinitrogen, respectively. Solvents were distilled from appropriate drying agents and stored over either molecular sieves (4 Å, for DCM and THF) or potassium mirrors. General reagents were obtained from Sigma-Aldrich or Fisher and purified by appropriate methods before use; precious metal salts were obtained from STREM. [RuHCl(CO)(PPh<sub>3</sub>)<sub>3</sub>],<sup>37</sup> <sup>t</sup>BuC≡P,<sup>38</sup> RMe<sub>2</sub>SiCH<sub>2</sub>PCL<sub>2</sub> (R = Me, Ph),<sup>23</sup> Me<sub>3</sub>SiC≡P,<sup>20,39</sup> and [Ru{P=CH(<sup>t</sup>Bu)}Cl(CO)(PPh<sub>3</sub>)<sub>2</sub>]<sup>13,15</sup> were prepared by literature methods. Unless otherwise stated, NMR spectra were recorded at 303 K on a Varian VNMRS 400 (<sup>1</sup>H, 399.50 MHz; <sup>13</sup>C, 100.46 MHz; <sup>19</sup>F, 375.87; <sup>31</sup>P, 161.71 MHz; <sup>29</sup>Si, 79.37 MHz); VNMRS 500 (<sup>1</sup>H, 499.91 MHz; <sup>13</sup>C, 125.72 MHz) or 600 (<sup>1</sup>H, 599.69 MHz; <sup>13</sup>C, 150.81 MHz; <sup>31</sup>P, 242.83 MHz) spectrometers were used in selected instances. All spectra are referenced to external Me<sub>4</sub>Si, 85% H<sub>3</sub>PO<sub>4</sub>, and CFCl<sub>3</sub> as appropriate. Carbon-13 spectra were assigned by recourse to the 2D (HSQC, HMBC) spectra; phosphalkenic proton and silicon shifts were determined indirectly by <sup>1</sup>H–<sup>31</sup>P and <sup>1</sup>H–<sup>29</sup>Si correlation (HMBC). Mass spectrometry was performed by Dr A. Abdul-Sada of the departmental service. Elemental analyses were obtained by Mr. S. Boyer of the London Metropolitan University Elemental Analysis Service.

**X-ray Diffraction Studies.** Single-crystal X-ray diffraction data were recorded on an Agilent Xcalibur Eos Gemini Ultra diffractometer with CCD plate detector using Mo K $\alpha$  ( $\lambda = 0.71073$ ) or Cu K $\alpha$  ( $\lambda = 1.54184$ ) radiation. Structure solution and refinement were performed using SHELXS<sup>40</sup> and SHELXL,<sup>40</sup> respectively, running under WinGX<sup>41</sup> or Olex2.<sup>42</sup>

**DFT Calculations.** Calculations were performed using Gaussian 09W, Revision C.01,<sup>43</sup> running on an Intel Core i5-2500 (quad, 3.3 GHz), equipped with 4 GB RAM; results were visualized using GaussView 5.0. Geometries were optimized with the hybrid density functional B3LYP, using the RECP basis set LanL2dz for Ru and 6-31G\*\* for all other atoms. Minima were characterized by frequency calculations, and calculated frequencies adjusted by standard scaling factors. NMR shielding tensors were calculated at the same level of theory with both the B3LYP and PBEPBE hybrid functionals using the GIAO method, and compared against those similarly calculated for the respective reference standards to derive chemical shifts.

**(*p*-Tol)Me<sub>2</sub>SiCH<sub>2</sub>Cl.** To a cooled (−10 °C), stirred ethereal solution (30 cm<sup>3</sup>) of ClMe<sub>2</sub>SiCH<sub>2</sub>Cl (10 cm<sup>3</sup>, 0.076 mol) was added a THF solution of *p*-TolMgBr (57 cm<sup>3</sup>, 1.33 M, 0.065 mol). After 45 min, the mixture was brought to reflux for 18 h, and then allowed to cool to ambient temperature with continued stirring. The solvents were removed by distillation at ambient pressure, and then the residue was distilled under reduced pressure (2.3 mbar, 55 °C) to afford (*p*-Tol)Me<sub>2</sub>SiCH<sub>2</sub>Cl as a colorless liquid (6.6 g, 43%), which was identified on the basis of literature data.<sup>44</sup> <sup>1</sup>H NMR (CDCl<sub>3</sub>): δ 0.41 (s, 6H, Si(CH<sub>3</sub>)<sub>2</sub>), 2.37 (s, 3H, CH<sub>3</sub>-Ar), 2.94 (s, 2H, CH<sub>2</sub>Cl), 7.21 (d, *J* = 7.71 Hz, 2H, Ar-H), 7.45 (d, *J* = 7.71, 2H, Ar-H). <sup>13</sup>C NMR (CDCl<sub>3</sub>): δ 4.3 (s, <sup>1</sup>*J*<sub>SiC</sub> = 54.1 Hz, Si(CH<sub>3</sub>)<sub>2</sub>), 21.6 (s Ar-CH<sub>3</sub>), 30.7 (s, CH<sub>2</sub>Cl), 128.98 (s, Ar-H), 133.9 (s, Ar-H). <sup>29</sup>Si NMR (CDCl<sub>3</sub>): δ −4.1.

**(*p*-Tol)Me<sub>2</sub>SiCH<sub>2</sub>PCL<sub>2</sub>.** Following from literature methods for related compounds,<sup>23</sup> TolMe<sub>2</sub>SiCH<sub>2</sub>Cl (6.6 g, 0.033 mol) in ether (15 cm<sup>3</sup>) was added, dropwise, to a stirring suspension of activated Mg (2.0 g, 0.08 mol) in ether (20 cm<sup>3</sup>), at a rate to maintain reflux. Stirring was continued while the reaction cooled to ambient temperature, and then for a further 2 h. The mixture was then filtered directly into an ethereal solution (20 cm<sup>3</sup>) of PCL<sub>2</sub> (4.5 cm<sup>3</sup>, 0.05 mol) held at −78 °C. The mixture was then stirred for 30 min at this temperature, before being allowed to warm to ambient temperature over the course of 18 h. The solution was filtered, and the residues were washed with Et<sub>2</sub>O (3 × 15 cm<sup>3</sup>); the combined filtrate was stripped of Et<sub>2</sub>O by distillation at ambient temperature to afford a colorless liquid (5.92 g, 67%). <sup>1</sup>H NMR (CDCl<sub>3</sub>): δ 0.48 (s, 6H SiMe<sub>2</sub>), 2.24 (d, <sup>2</sup>*J*<sub>PH</sub> = 15.2 Hz, CH<sub>2</sub>), 2.37 (s, 3H, Me), 7.22 (d, <sup>3</sup>*J*<sub>C-H</sub> = 7.4 Hz, Ar-H), 7.44 (d, <sup>3</sup>*J*<sub>C-H</sub> = 7.4 Hz, Ar-H). <sup>13</sup>C{<sup>1</sup>H} NMR (CDCl<sub>3</sub>): δ −1.33 (s, SiMe<sub>2</sub>), 21.6 (s, CH<sub>3</sub>), 35.2 (d, <sup>1</sup>*J*<sub>C-P</sub> = 61 Hz, CH<sub>2</sub>), 129.1 (s, Ar-H), 133.1 (d, <sup>3</sup>*J*<sub>C-P</sub> = 4 Hz, Si-C), 133.7 (Ar-H), 140.0 (s, C-Me). <sup>29</sup>Si NMR (CDCl<sub>3</sub>): δ −6.7. <sup>31</sup>P NMR (CDCl<sub>3</sub>): δ 203.3.

**(*p*-Tol)Me<sub>2</sub>SiC≡P.** As previously described for RMe<sub>2</sub>SiC≡P (R = Me, Ph),<sup>20,38</sup> TolMe<sub>2</sub>SiCH<sub>2</sub>PCL<sub>2</sub> (0.595 g, 2.4 mmol) as a solution in toluene was added to a toluene suspension of AgOTf (1.26 g, 4.9 mmol); after this mixture was stirred for 10 min, DABCO (0.550 g, 4.9 mmol) was added as a solution in toluene. After being stirred for 1 h, the mixture was filtered and then calibrated for concentration by integration of its <sup>31</sup>P{<sup>1</sup>H} NMR resonance (δ<sub>p</sub> 103.3) against that of fully relaxed (d<sub>1</sub> = 150 s) PPh<sub>3</sub>. Samples were stored below 5 °C (<1 week) and recalibrated before use.

**[Ru{P=CH(SiMe<sub>2</sub>R)}Cl(CO)(PPh<sub>3</sub>)<sub>2</sub>] (R = Me, 2; Ph, 3; *p*-Tol, 4).** In a typical reaction, to a stirring suspension of [RuHCl(CO)(PPh<sub>3</sub>)<sub>3</sub>] (1.5 g, 1.53 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (15 cm<sup>3</sup>) was added an excess (1.3 equiv) of RMe<sub>2</sub>SiC≡P as a solution in toluene (ca. 25 cm<sup>3</sup>). After this mixture was stirred for 1 h, the solvent was removed under reduced pressure to afford an orange/brown residue, which was washed vigorously with *n*-hexane (3 × 10 cm<sup>3</sup>). The solvent was then removed by filtration, to afford a yellow to orange solid, which was dried in vacuo.

**Data for 2.** Yield, 95%. <sup>1</sup>H NMR (C<sub>6</sub>D<sub>6</sub>, 499.9 MHz): δ<sub>H</sub> 7.92–7.85 (m, 12 H, PAR<sub>3</sub>), 7.39 (s, 1H, P=CH), 7.08–6.98 (m, 18 H, PAR<sub>3</sub>), 0.18 (s, *J*<sub>SiH</sub> 6.5 Hz, 9 H). <sup>13</sup>C{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>) δ<sub>C</sub> 203.0 (m, C≡O), 168.0 (br, CH, P=CH), 134.1, 132.2, 127.6 (m, CH, PAR<sub>3</sub> × 3), 0.9 (d, *J*<sub>CP</sub> 6.4 Hz, Si(CH<sub>3</sub>)<sub>2</sub>). <sup>31</sup>P{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>): δ<sub>p</sub> 34.6 (d, *J*<sub>PP</sub> 8 Hz), 548.5 (t, *J*<sub>PP</sub> 8 Hz). <sup>29</sup>Si{<sup>1</sup>H} NMR (C<sub>6</sub>D<sub>6</sub>): δ<sub>Si</sub> −9.4. ν<sub>CO</sub> = 1920 cm<sup>−1</sup>. High-res ESI+MS:  $m/z$  982.1582 [M]<sup>+</sup> (Err = 4.57 ppm).

## ■ ASSOCIATED CONTENT

### ● Supporting Information

Final atomic positions of optimized geometries for compounds 1–5 and 7 in xyz format; frontier orbital plots for 1–4; charge distribution plots for 1 and 2; and crystallographic data, in CIF format, for 2 (CCDC 1036624), 3 (CCDC 1036625), and 4 (CCDC 1036626). The Supporting Information is available free of charge on the ACS Publications website at DOI: 10.1021/om5012177.

## ■ AUTHOR INFORMATION

### Corresponding Author

\*E-mail: i.crossley@sussex.ac.uk.

### Author Contributions

<sup>†</sup>V.K.G. and N.T. contributed equally to the work.

### Notes

The authors declare no competing financial interest.

## ■ ACKNOWLEDGMENTS

We thank the Royal Society, Leverhulme Trust (F/00 230/AL, studentship to N.T.), and University of Sussex (studentship to V.K.G.) for financial support. I.R.C. gratefully acknowledges the award of a Royal Society University Research Fellowship. We thank Dr. I. J. Day (Sussex) for collection of <sup>13</sup>C{<sup>31</sup>P} NMR spectra for compound 3, Dr. A. Abdul-Sada (Sussex) for collection of high-resolution MS data for compounds 12–14, and Dr. M. P. Coles (Sussex/Wellington) for assistance with the X-ray structural solution for compound 2.

## ■ DEDICATION

Dedicated to the memory of Prof. Michael F. Lappert, an inspiring colleague.

- (34) Compound **14** forms alongside decomposition products, as observed by *in situ* NMR studies. Separation from other metal-containing species is effected by dissolution in hexane, pentane, or dry ethanol; however, appreciable solubility in these solvents, alongside sensitivity to more “invasive” purification methods, has precluded separation from free PPh<sub>3</sub> and other trace impurities. The parent ion is apparent from high-resolution mass spectrometry, and the species is otherwise characterized spectroscopically *in situ*. Compound **14** exhibits an unequivocally characteristic <sup>31</sup>P{<sup>1</sup>H} NMR spectrum (cf. compounds **5–13**), heteronuclear correlation experiments (<sup>31</sup>P–<sup>1</sup>H, <sup>13</sup>C–<sup>1</sup>H, <sup>29</sup>Si–<sup>1</sup>H HMBC, and <sup>13</sup>C–<sup>1</sup>H HSQC) allowing assignment of the key <sup>1</sup>H and <sup>13</sup>C resonances. A single <sup>19</sup>F-containing species is apparent and is thus unequivocally assigned.

- (36) In the CF<sub>3</sub>-substituted pyrazolates, appreciable variation in nucleophilicity between the two nitrogen centers is probable, such that the more encumbered site would be least reactive; for [pz<sup>fbu</sup>]<sup>−</sup> the situation will be less pronounced, but also reversed. Thus, while for [pz<sup>fbu</sup>]<sup>−</sup> the same isomer might reasonably result from either steric shielding of the metal or preferential attack at phosphorus, for the fluorinated systems attack at phosphorus by the more reactive nitrogen should place the CF<sub>3</sub> moiety distal from phosphorus; sterics would then preclude coordination to the metal. Notwithstanding, reversible attack at phosphorus, cannot be discounted, which may allow for formation of the observed isomer.
