Received November 16, 2010

The reaction of LAIH₂ (L = HC(CMeNAr)₂, Ar = $2,6-iPr_2C_6H_3$) (1) with 3-methylphenylboronic acid and 3-fluorophenylboronic acid resulted in the boroxine-linked aluminum compounds LAI[OB(3-CH₃C₆H₄)]₂(μ -O) (2) and LAI[OB(3-FC₆H₄)]₂(μ -O) (3), respectively. LAI[OB(2-PhC₆H₄)(OH)]₂ (4) was synthesized by the reaction of 1 with 2-biphenylboronic acid. Compound 4 is the intermediate analogue to those, which we postulated for the formation of 2 and 3. The reaction of 1 with 3-hydroxyphenylboronic acid resulted in the first metal benzoboroxole oxide LAI[OB(o-CH₂O)C₆H₄]₂ (5), which is formed from a compound with B-(OH)₂ and C-OH functionalities.

Introduction

Boroxines are polymeric materials prepared from organoboronic acids by dehydration.¹ They are not only of fundamental academic interest (e.g., structural investigations, electrochemistry, intermediate products, etc.) but also important for industrial applications (flame retardants for light metals, lithium ion battery materials, etc.).² In 2005, Yaghi et al. reported the first crystalline arylboroxine-based covalent organic framework material.³ Furthermore, aluminum heterometallic oxides have attracted much interest due to their broad applications in chemical processes.⁴ We reasoned that aluminum substituted boroxines containing the Al–O–B moiety might have unusual properties compared to those of boroxines. However, only two examples of aluminum substituted boroxines were reported due to limited synthetic methods.^{5,6}

Inorganic Chemistry

Benzoboroxoles are highly useful synthetic intermediates for transition metal catalyzed cross-coupling reactions and are widely utilized in medicinal and materials chemistry.⁷ In 2006, we reported a rare aluminum spirocyclic hybrid with an inorganic B_2O_3 and an organic C_3N_2 core.⁶ In that paper, we explained the annelation mechanism only by DFT calculation without further experimental proof. The electronic and sterical effects of bulky β -diketiminato ligands are usually used to stabilize the metal center to avoid condensation of molecules and to form unique compounds. It is possible to change selectively the functionalities at the Al center by using those ligands. Herein, we report a series of novel structures bearing the Al-O-B unit, give solid experimental proof of the annelation mechanism, and discuss a one step route to the first metal benzoboroxole oxide by the reaction of 3-hydroxyphenylboronic acid with aluminum dihydride LAIH₂ $(1; L = HC(CMeNAr)_2, Ar = 2, 6-iPr_2C_6H_3)$ supported by the bulky β -diketiminato ligand.

Scheme 1. Preparation of Compounds 2 and 3

Experimental Section

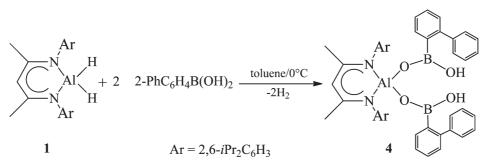

General Procedures. All manipulations were carried out under a purified nitrogen atmosphere using Schlenk techniques or inside a Mbraun MB 150-GI glovebox. All solvents were distilled from Na/benzophenone ketyl prior to use. Commercially available chemicals were purchased from Aldrich, Fluka and used as received. LH⁸ and LAIH₂⁹ were prepared as described in the literature. Elemental analyses were performed by the Analytical Instrumentation Center of the Peking University. ¹H NMR spectra were recorded on Bruker AM 400 spectrometer. The infrared spectrum was recorded on a Perkin-Elmer spectrophotometer. Melting points were measured in sealed glass tubes.

Synthesis of LAI[OB(3-CH₃C₆H₄)]₂(μ -O) (2). A solution of 1 (0.223 g, 0.5 mmol) in toluene (10 mL) was added drop by drop to a solution of 3-methylphenylboronic acid (0.136 g, 1 mmol) in toluene (10 mL) at 0 °C. After the addition was complete, the reaction mixture was allowed to warm to room temperature, and stirring was continued overnight. The solvent was removed *in vacuo*. The solid was extracted with *n*-hexane (30 mL), and the extract was stored at room temperature for 2 days to afford **2** as colorless crystals. An additional crop of **2** was obtained from the mother liquor. Total yield, 0.296 g (85.1%); mp, 212 °C. ¹H NMR (399.13 MHz, CDCl₃, 25 °C, TMS): δ 7.81–7.12 (m, 14 H, Ar-*H*), 5.48 (s, 1 H, γ -*H*), 3.44 (sept, ³J_{H-H} = 6.8 Hz, 4 H,

CHMe₂), 2.39 (s, 6 H, Me-C₆H₅), 1.60 (s, 6 H, Me), 1.33 (d, ${}^{3}J_{H-H} = 6.8$ Hz, 12 H, CH Me_{2}), 1.24 ppm (d, ${}^{3}J_{H-H} = 6.8$ Hz, 12 H, CH Me_{2}). C₄₃H₅₅AlB₂N₂O₃ (696.51) Calcd: C, 74.15; H, 7.96; N, 4.02. Found: C, 74.01; H, 7.95; N, 4.01%.

Synthesis of LAI[**OB**(**3**-**FC**₆**H**₄)]₂(*μ*-**O**) (**3**). The preparation of **3** is like that of **2** from **1** (0.223 g, 0.5 mmol) and 3-fluorophenylboronic acid (0.140 g, 1 mmol). Product **3** was isolated as colorless crystals. Total yield, 0.306 g (87%); mp, 221 °C. ¹H NMR (399.13 MHz, C₆D₆, 25 °C, TMS): δ 7.88–7.89 (m, 14 H, Ar-*H*), 4.87 (s, 1 H, *γ*-*H*), 3.26 (sept, ³*J*_{H-H} = 6.8 Hz, 4 H, C*H*Me₂), 1.34 (s, 6 H, *Me*), 1.11 (d, ³*J*_{H-H} = 6.8 Hz, 12 H, CH*Me*₂), 1.09 ppm (d, ³*J*_{H-H} = 6.8 Hz, 12 H, CH*Me*₂). ¹⁹F NMR (399.13 MHz, C₆D₆, 25 °C, CF₃COOH): *δ* –36.65 ppm. C₄₁H₄₉AlB₂F₂N₂O₃ (704.44) Calcd: C, 69.91; H, 7.01; N 3.98. Found: C, 69.35; H, 7.01; N, 3.76%.

Synthesis of LAI[OB(2-PhC₆H₄)(OH)]₂ (4). A solution of 1 (0.223 g, 0.5 mmol) in toluene (10 mL) was added drop by drop to a suspension of 2-biphenylboronic acid (0.198 g, 1 mmol) in toluene (10 mL) at 25 °C. After the addition was complete, the reaction mixture was kept stirring for 72 h. The solvent was removed *in vacuo*. The solid was extracted with *n*-hexane (30 mL), and the extract was stored at room temperature for 3 days to afford 4 as colorless crystals. Total yield, 0.383 g(91.4%); mp, 253 °C. ¹H NMR (399.13 MHz, CDCl₃, 25 °C, TMS): δ 7.52–6.99 (m, 24 H, Ar-H), 4.90 (s, 1 H, γ -H), 3.25 (sept, ³J_{H-H} = 6.8 Hz, 4 H, CHMe₂), 1.48 (s, 6 H, *Me*), 1.19 (d, ³J_{H-H} = 6.8 Hz, 12 H, CHMe₂), 1.08 ppm (d, ³J_{H-H} = 6.8 Hz, 12 H, CHMe₂). IR(KBr, cm⁻¹): $\bar{\nu}$ 3422 (w). C₅₃H₆₁AlB₂N₂O₄ (838.64) Calcd: C, 77.27; H, 7.35; N, 3.34. Found: C, 75.90; H, 7.33; N, 3.34%.

Synthesis of LAI[OB(*o*-CH₂O)C₆H₄)]₂ (5). The preparation of 5 is like that of 4 from 1 (0.223 g, 0.5 mmol) and 3-hydroxyphenylboronic acid (0.152 g, 1 mmol). Product 5 was isolated as colorless crystals. Total yield, 0.292 g (82.4%); mp, 185 °C. ¹H NMR (399.13 MHz, C₆D₆, 25 °C, TMS): δ 7.59-6.90 (m, 14 H, Ar-H), 5.16 (s, 1 H, γ -H), 4.77 (s, 4 H, CH₂), 3.69 (sept, ³J_{H-H} = 6.8 Hz, 4 H, CHMe₂), 1.77 (s, 6 H, Me), 1.45 (d, ³J_{H-H} = 6.8 Hz, 12 H, CHMe₂), 1.23 ppm (d, ³J_{H-H} = 6.8 Hz, 12 H, CHMe₂). C₄₃H₅₃AlB₂N₂O₄ (710.50) Calcd: C, 72.69; H, 7.52; N 3.94. Found: C, 72.49; H, 7.58; N, 3.71%.

Single Crystal X-Ray Structure Determination and Refinement. Single crystals of 2, 3, 4, and 5 were mounted with glue on a glass fiber, and crystal data were collected on the Rigaku AFC10 Saturn724 + (2 × 2 bin mode) diffractometer equipped with graphite-monochromated Mo K α radiation ($\lambda = 0.710747$ Å). Empirical absorption correction was applied using the SA-DABS program.¹⁰ The structures were solved by direct methods¹¹ and refined by full-matrix least-squares on F^2 using the SHELXL-97 program.¹² The crystal structure of **3** contains a seriously disordered solvent molecule, which was assigned to hexane. Except those of solvent of **3**, all non-hydrogen atoms were refined anisotropically, and the hydrogen atoms were generated geometrically and treated by an independent and constrained refinement. The carbon atoms of the solvent molecules in **3** were refined isotropically, and the hydrogen atoms of the solvent molecules were not included in the refinement. A summary of the crystal data is given in Table 1.

Results and Discussion

The reaction of **1** with 3-methylphenylboronic acid, 3-fluorophenylboronic acid (Scheme 1), 2-biphenylboronic acid (Scheme 2), and 3-hydroxyphenylboronic acid (Scheme 3) in a molar ratio of 1:2 resulted in the products LAI[OB(3-CH₃C₆H₄)]₂(μ -O) (**2**), LAI[OB(3-FC₆H₄)]₂(μ -O) (**3**), LAI-[OB(2-PhC₆H₄)(OH)]₂ (**4**), and LAI[OB(o-CH₂O)C₆H₄)]₂ (**5**), respectively. During the course of these reactions, hydrogen gas evolution was observed. Compounds **2**, **3**, **4**, and **5** were isolated after growing colorless crystals from the concentrated *n*-hexane solutions. They are soluble in toluene, benzene, and trichloromethane.

Compounds 2, 3, 4, and 5 were characterized by ¹H NMR investigation in CDCl₃ and C_6D_6 solutions, as well as by elemental analysis. Compound 3 was additionally characterized by ¹⁹F NMR. The ¹H NMR spectra of 2, 3, 4, and 5 exhibit one set of resonances for the aryl group both on boron and on the ligand, indicating symmetric molecules. Compound 2

shows the *Me*-Ph resonances at δ 2.39 ppm in a 6:1 ratio with the γ -C-H proton. Compound **3** exhibits one resonance at δ -36.63 ppm in the ¹⁹F NMR spectrum. The IR spectrum of compound **4** shows a strong band at $\bar{\nu}$ 3422 cm⁻¹, which is attributed to the hydroxyl group attached to the boron atom,

and it is quite close to that (3494 cm^{-1}) reported by Barba et al.¹³

For the progress of the two reactions to **2** and **3**, we assumed two similar concerted mechanisms through intermediate **A** shown in Scheme 1. The formation of **2** and **3** through intermediate **A** is driven by the exothermic Al–O bond enthalpy. The increase of the proton acidity of the intermediate LAl[OB(3-MeC₆H₄)OH]₂ leads to the elimination of water under AlO₃B₂ ring formation. Compounds **2** and **3** are rare examples containing a spiro-centered aluminum atom, where the inorganic AlO₃B₂ ring is fused to the organic C₃N₂ part. The less acidic protons of the OH groups of the 3-MeC₆H₄B(OH)₂ are reactive enough to form the Al–O bonds, while those of the 2-PhC₆H₄B(OH)₂ react only with one OH group to yield LAl[OB(2-PhC₆H₄)(OH)]₂ (**4**) containing two terminal boron hydroxyl groups.

To study the steric effect for the AlO₃B₂ rings formation, we selected 2-biphenylboronic acid as a precursor molecule. The reaction did not proceed under dehydration like those observed for **2** and **3**. The bulky 2-biphenyl groups on each of the boron atoms repel each other, which makes the two B–OH groups too far away to react with each other under elimination of H₂O. So one of the two hydroxyl groups on each boron remained. The formation of **4** strongly supports the mechanism we postulated for the formation of compounds **2** and **3**. The structure of **4** is quite similar to that of intermediate **A**, which we assumed in the reaction of producing compounds **2** and **3**.

Furthermore, we were interested in extending these investigations by using a precursor bearing the $B(OH)_2$ as well as the C–OH functionality. By the reaction of 3-hydroxyphenylboronic acid with 1, we obtained a novel organoboron heterocyle, 5, containing two C₃OB five-membered rings.

X-ray quality single crystals of **2**, **3**, **4**, and **5** were obtained from a *n*-hexane solution at room temperature. Compounds **2** and **5** crystallize in the monoclinic space group $P2_1/n$; **3** forms crystals in the orthorhombic space group *Pbcn* and **4** in the triclinic $P\overline{1}$ space group. The molecular structures are shown in Figures 1, 2, 3, and 4, respectively, and the selected bond lengths and angles are shown in Tables 2, 3, 4, and 5. For the structures of **2** and **3**, one aluminum atom, two boron atoms, and three oxygen atoms form a six-membered planar AlO₃B₂ ring. The central aluminum atom is located in the spirocyclic center of the two fused six-membered rings (C₃N₂Al and AlO₃B₂). The Al–O bond lengths (av 1.739 Å

for 2 and 3) are longer than the Al–OH bond distance (av 1.705 Å) in LAl(OH)₂,¹⁴ which is quite close to those of 4 (av 1.706 Å) and 5 (av 1.710 Å). The O-Al-O angles (104.00(8)° for 2 and $103.53(10)^{\circ}$ for 3) are smaller than that in LAl(OH)₂ $(115.38(8)^{\circ})$ and those in 4 $(118.20(6)^{\circ})$ and 5 $(109.66(11)^{\circ})$. The difference in bond lengths and bond angles of 2 and 3 from those of 4 and 5 is due to a certain strain within the sixmembered rings of 2 and 3. The two Me groups at the aryl groups of 2 are in a cis position of the C_2 axis, which exhibits a nonsymmetric molecule, but due to the free rotation of the C–B σ bond, the molecule is symmetric in solution, which was shown by ¹H NMR at room temperature. The structure of 4 contains the $Al-(O-B-OH)_2$ moiety with the terminal boron hydroxyl groups. The sum of the inner angles of the two C_3BO five-membered rings in 5 are 539.95° and 540.05°, respectively, which is quite close to that of the planar pentagon of 540°. The most distinct characters of 5 are the benzoboroxole moieties. Compound 5 is the first benzoboroxole compound formed in a one step synthesis. The known benzoboroxoles have been prepared mostly by a salt elimina-tion reaction of borate with dianionic species^{15,16} in two or three steps. Moreover, compound 5 is the first example of a metal benzoboroxole oxide.

Conclusion

In summary, by selecting the groups with different substituents on boron, the reactions of $LAlH_2$ with aryl boronic acids result in cyclic or acyclic boroxines. The latter contains terminal boron hydroxyl groups. $LAlH_2$ reacts with 3-hydroxyphenylboronic acid under the formation of the first metal benzoboroxole oxide. This benzoboroxole is formed by an intramolecular reaction of $B-(OH)_2$ and C-OH functionalities.
