ABSTRACT

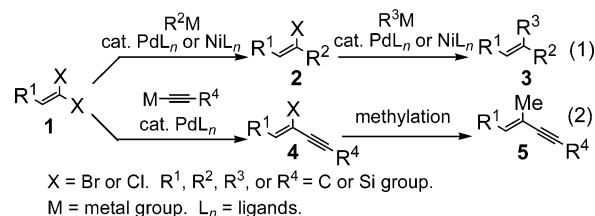

trans-Selective ($\geq 98\%$) monoalkynylation of 1,1-dibromo-1-alkenes and 1,1-dichloro-1-alkenes catalyzed by $\text{Cl}_2\text{Pd}(\text{DPEphos})$ followed by stereospecific methylation with Me_2Zn or MeZnX ($\text{X} = \text{Cl or Br}$) catalyzed by $\text{Pd}(\text{}^t\text{Bu}_3\text{P})_2$ provides an efficient and stereoselective ($\geq 98\%$) route to **5**, convertible to a wide variety of enynes and conjugated dienes. In the cases of 1,1-dibromo-1-alkenes, the Sonogashira alkynylation may also be satisfactory, but it is distinctly less satisfactory than the alkynylzinc reaction in cases where 1,1-dichloro-1-alkenes are used.

Reported herein is a highly selective synthesis of (*E*)-3-methyl-3-en-1-ynes via two-stage Pd-catalyzed cross-coupling¹ of 1,1-dihalo-1-alkenes (**1**) containing Br or Cl (eq 2 in Scheme 1, where M is a Zn group and R⁴ is a Si group). Although various protocols for the *trans*-selective substitution of **1** to **2** and/or **3** have been known since 1987,^{2–7} selective conversion of **1** to **5** via **4** appears to be unprecedented, the

only reported example of Pd- or Ni-catalyzed methylation of **2** to produce **3** being that of (*Z*)-bromostilbene with Me_4Sn .^{5c} In more recent papers,^{7a,b} *trans*-selective Sonogashira alkynylation^{7c} of $\text{PhCH}_2\text{CH}_2\text{CH}=\text{CBr}_2$ with $\text{HC}\equiv\text{CSiMe}_3$

followed by alkylation with a couple of alkyllmagnesium chlorides catalyzed with $\text{Cl}_2\text{Ni}(\text{dppp})^{2a}$ was reported, but methylation was not achieved. Also known are a few alkylation reactions of (Z)-3-bromo-3-en-1-yne not involving Pd or Ni catalysts.⁸ Interestingly, these reactions predominantly produced the stereoinverted (Z)-3-alkyl-3-en-1-yne.

Conjugated oligoenes and oligoenynes containing stereo- and regiodefined methyl-branched trisubstituted alkenes represent a large number of natural products and related compounds of biological and medicinal significance. We recently reported an efficient and selective “head-to-tail” (H-to-T)⁹ route to carotenoids involving Zr-catalyzed carboalumination and Pd-catalyzed alkenyl–alkenyl coupling.¹⁰ However, it is also very desirable to develop complementary “tail-to-head” (T-to-H)⁹ routes to cope with various structural features, including the presence of proximal asymmetric carbon and heterofunctional groups. One such protocol¹¹ that has been used with considerable success involves regioselective hydrozirconation of 2-alkynes followed by Pd-catalyzed cross-coupling, and the required alkynes are often prepared via Corey–Fuchs reaction¹² of aldehydes followed by elimination and methylation. In such cases, however, stereoselective two-stage substitution of 1,1-dihaloalkenes would be more straightforward.

^a By GLC with isolated yields in parentheses. ^b Two other byproducts were formed. ^c From MeLi and ZnCl_2 . ^d From MeMgBr and ZnCl_2 . ^e $\text{Z} = \text{tert-butyl}$ dimethylsilyl.

As implied by a related investigation mentioned above,⁸ stereospecific methylation of (Z)-3-halo-3-en-1-yne (4) proved to be very challenging. Methylation of (Z)-(n-C₉H₁₉)-CH=C(Br)C≡CSiMe₃ (4a) with MeMgBr in the presence of either 5 mol % $\text{Cl}_2\text{Ni}(\text{dppp})$ or 5 mol % $\text{Pd}(\text{PPh}_3)_4$ was not clean in our hands. It was hence not a practically useful reaction. On the other hand, the Pd-catalyzed reaction of 4a with Me_2Zn proceeded to give the methylated product in high yields. As indicated by the results summarized in Table 1, however, all catalysts tested except $\text{Pd}(\text{Bu}_3\text{P})_2$,^{13,14} namely, $\text{Pd}(\text{PPh}_3)_4$, $\text{Cl}_2\text{Pd}(\text{dppf})$, $\text{Cl}_2\text{Pd}(\text{DPEphos})$ [DPEphos = bis-(2-diphenylphosphinophenyl) ether],¹⁵ and $\text{Cl}_2\text{Pd}(\text{TFP})_2$ [TFP

(Z)- stereoisomeric mixtures, were observed. The results summarized in Table 2 indicate the following. First, the reaction of either 1,1-dibromo- or 1,1-dichloro-1-alkenes with $\text{ClZnC}\equiv\text{CSiMe}_3$ in the presence of 5 mol % $\text{Cl}_2\text{Pd}(\text{DPEphos})^{15}$ proved to be the most satisfactory procedure, leading to the desired monoalkynylation products in $\geq 84\%$ yields except in the reaction of 1,1-dichloro-1-octene, where the product yield was 65%. Second, the reaction of 1,1-dibromo-1-alkenes is nearly 100% stereoselective. The extent of dialkynylation in each case is $<10\%$, corresponding to the consumption of 0.2 molar equiv of $\text{ClZnC}\equiv\text{CSiMe}_3$ relative to the dibromide.

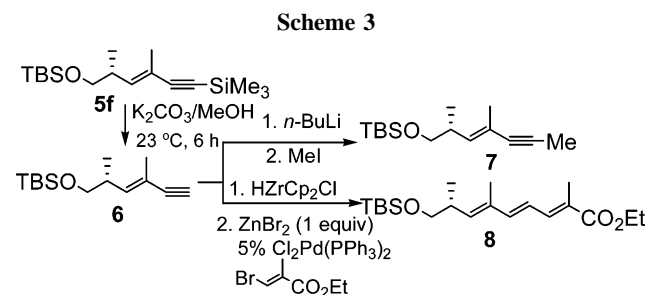

On the other hand, alkynylation of 1,1-dichloro-1-alkenes displays more widely varied results. Even with $\text{Cl}_2\text{Pd}(\text{DPEphos})$, the Sonogashira alkynylation using $\text{HC}\equiv\text{CSiMe}_3$ (1.2–1.3 molar equiv), CuI (5 mol %), $\text{Cl}_2\text{Pd}(\text{DPEphos})$ (5 mol %), and $^t\text{Pr}_2\text{NH}$ (2 equiv) proceeded slowly at 23 °C and was accompanied by detectable formation of the (*E*)-isomer. Third, dppf may be nearly as effective as DPEphos in some cases but is at least somewhat inferior to the latter, while PPh_3 , TFP , dppb , and $^t\text{Bu}_3\text{P}$ are distinctly inferior to DPEphos with some exceptions. Fourth, the use of bulky silyl groups, e.g., Ph_3Si and $^t\text{Pr}_3\text{Si}$, is effective in avoiding dialkynylation, even with highly demanding substrates such as **4f**.

Despite the favorable results presented above, the *trans*-selective monoalkynylation protocol reported herein is still of limited scope with respect to R^4 in **4** and **5**. In contrast, with the favorable results observed with silyl-substituted alkynes, extensive dialkynylation has been observed with other alkynes and their zinc derivatives, including those containing Me, Ph, PhCH=CH , and TBSOCH_2 under various conditions, even though favorable results such as those shown in Scheme 2 were also observed in some exceptional cases.

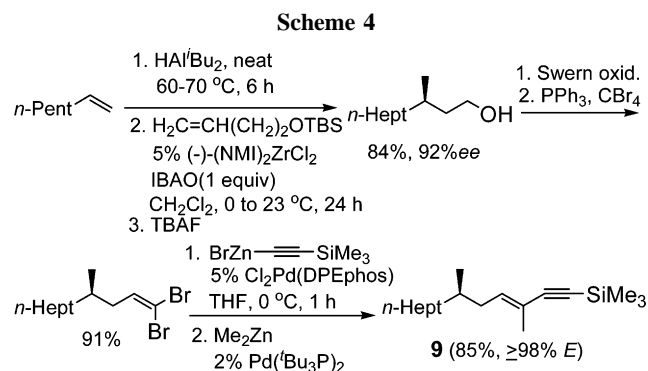

Further development is clearly desirable. In the meantime, however, various 3-bromo- and 3-methyl-substituted 1-tri-alkylsilyl-3-en-1-ynes preparable by the process reported herein may be desilylated and further converted into a wide

variety of their derivatives, as exemplified by the conversion of **5f** to **6** via desilylation with $\text{K}_2\text{CO}_3\text{--MeOH}$ and then to **7** via lithiation with *n*-BuLi and methylation with MeI both in nearly quantitative yields. Conversion of **6** into a trienonic ester **8** in one pot in 94% yield as a single stereoisomer ($\geq 98\%$) is also noteworthy (Scheme 3). The potential

synthetic value of the method reported herein is further demonstrated by the five-step synthesis of enyne **9** ($\geq 98\%$ (*E*)- and 92% ee) from 1-heptene in 65% overall yield (Scheme 4). This enyne can potentially serve as a convenient

intermediate for the synthesis of a recently reported potent topoisomerase inhibitor, topostatin.¹⁸
