Nitrogen fixation using transition metals is a fascinating process. We have already reported on the incorporation of molecular nitrogen into organic compounds using a titanium–nitrogen complex reported by Yamamoto. We developed a novel titanium-catalyzed nitrogenation procedure using TiCl₄ in the presence of an excess amount of Li and TMSCl. In this reaction, a 1 atm pressure of nitrogen gas can be used and the reaction proceeds at room temperature. The procedure is very simple. A THF solution of TiCl₄ or Ti(O^{*i*}Pr)₄ (1 equiv.), Li (10 equiv.), and TMSCl (10 equiv.) was stirred under an atmosphere of nitrogen at room temperature overnight to give titanium–nitrogen complexes. Although the structures of the titanium–nitrogen complexes have not yet been determined, they would consist of N(TMS)₃, X₂TiN(TMS)₂, and XTi=NTMS. Using this procedure, various heterocycles, such as indole, quinoline, pyrrole, pyrrolizine, and indolizine derivatives, could be synthesized from molecular nitrogen in good-to-moderate yields as a stoichiometric reaction based on a titanium complex by a one-pot reaction. Furthermore, monomorine I and pumiliotoxin C were synthesized from molecular nitrogen as a nitrogen source. This procedure was further extended for the syntheses of heterocycles using a catalytic amount of titanium complex; also, indole and pyrrole derivatives were obtained in high yields.

Since the discovery by Vol'pin and Shur that molecular nitrogen could be fixed by transition metals¹ and reducing agents under mild conditions, various systems of nitrogen fixation have been reported.² In 1967, Yamamoto reported on the synthesis of a cobalt-nitrogen complex³ and then a titanium-nitrogen complex.⁴ Hidai⁵ and Bercaw⁶ later reported on the synthesis of a molybdenum-nitrogen complex and a zirconiumnitrogen complex, respectively. However, there have been few reports on the incorporation of molecular nitrogen into organic compounds. In 1968, Vol'pin reported the synthesis of aniline from Cp2TiCl2 and phenyllithium under a high pressure of nitrogen (Eq. 1).⁷ Later, van Tamelen succeeded to obtain diethylamine and banzonitrile from diethyl ketone and benzoyl chloride, respectively, using Cp₂TiCl₂ and Mg under nitrogen (Eq. 2).8 In 1977, Chatt synthesized pyrrolidine and isopropylamine from 1,4-dibromobutane and acetone, respectively, using a molybdenum- or tungsten-nitrogen complex (Eqs. 3 and 4).⁹ Hidai et al. synthesized pyrrole from a tungsten-nitrogen complex (Eq. 5).¹⁰

These results prompted us to utilize molecular nitrogen in organic synthesis. Yamamoto reported on the synthesis of a very interesting titanium–nitrogen complex 1 from TiCl₄ or TiCl₃ and Mg as a reducing agent (Eq. 6).⁴ In this reaction, the nitrogen–nitrogen triple bond was cleaved by a titanium complex and a reducing agent to give a Ti–N complex. The result is very attractive for the synthesis of nitrogen heterocycles from molecular nitrogen because one nitrogen can be intro-

duced into the molecule. Sobota reported that the reaction of 1 with CO₂ gave titanium–isocyanate complex 2 (Eq. 7).¹¹

Since the handling of the latter complex 2 was easier than that of 1, we used 2 as a nitrogenation agent, and succeeded to synthesize various heterocycles (Eqs. 8 and 9).12a-e Although the synthesis of heterocycles using titanium-nitrogen complex 2 was achieved, an extension of this reaction to a catalytic reaction based on a transition metal was difficult because titanium-nitrogen complexes 1 and 2 were used after their isolation. Thus, various attempts were made, and we succeeded to develop a titanium-catalyzed nitrogen fixation method using TiX₄-TMSCl-Li.^{12f,g} That is, a THF solution of TiCl₄ was stirred in the presence of excess amounts of TMSCl and Li overnight under an atmosphere of nitrogen to give titanium-nitrogen complexes 7a that would contain a titanium-imide complex, a titanium-amide complex, and N(TMS)₃.¹³ After the hydrolysis of titanium-nitrogen complexes 7a with 10% HCl, excess amounts of PhCOCl and K2CO3 were added and the solution was stirred overnight. After the usual workup, benzamide was obtained in more than 100% yield based on TiCl₄ (Scheme 1). This means that the reaction proceeds catalytically with regard to TiCl₄.

Nirtogenation-Carbonylation

Nitrogenation-Transmetalation

Since molecular nitrogen can be fixed by this method and it is a very simple procedure, it was applied to the synthesis of heterocyclic compounds as a stoichiometric reaction.

Results and Discussion

Effects of Titanium Complexes and Reducing Agents for Nitrogen Fixation. We previously examined the effect of various reducing agents,^{12f,g} such as Mg, Na, K, Zn, and Li,

for nitrogen fixation, and it was found that Li gave good results. In this study, the effects of various titanium complexes were examined for nitrogen fixation. To measure the amount of fixed nitrogen, titanium–nitrogen complexes 7 were hydrolyzed with aqueous HCl to be converted into NH_4Cl , which reacted with benzoyl chloride in the presence of K_2CO_3 to give benzamide. The amount of nitrogen fixed by this method was estimated by the yield of benzamide. The results are given in Table 1.

A THF solution of TiCl₄ (1 equiv.), Li (10 equiv.), and TMSCl (10 equiv.) was stirred under an atmosphere of nitrogen overnight to give a black solution of titanium–nitrogen complexes **7a**, which was hydrolyzed with 10% HCl. To this solution was added a benzene solution of excess amounts of PhCOCl (10 equiv.) and K₂CO₃, and the solution was stirred at room temperature overnight to give benzamide in 96% yield (Table 1, run 1). When Cp₂TiCl₂ was used as a titanium complex, nitrogen could be fixed, but the results were not satisfactory. A low-valent titanium complex prepared from Ti(O^{*i*}Pr)₄ and Grignard reagent, which was reported by Sato,¹⁴ gave only a small amount of benzamide. It was very interesting that titanium–nitrogen complexes **7b**, prepared from Ti(O^{*i*}Pr)₄ instead of TiCl₄, gave benzamide in 91% yield (run 4).

Synthesis of Indole and Quinoline Derivatives from 1.3-Diketone Bearing a Keto-Carbonyl Group in a Tether at the 2-Position. Since titanium-nitrogen complexes 7 were easily obtained from TiCl₄ or Ti(OⁱPr)₄, TMSCl, and Li under nitrogen, an experiment was carried out to determine whether fixed nitrogen can be incorporated into organic compounds.^{12h} As a model compound, cyclohexenone derivative 9 was chosen. To a THF solution of titanium-nitrogen complexes 7a, which was prepared from TiCl₄ (1 equiv.), TMSCl (10 equiv.), and Li (10 equiv.) in THF under nitrogen, was added enol triflate 9a, and the whole solution was refluxed overnight. After the usual workup, enaminone 10 was obtained in 35% yield (Table 2, run 1). This means that fixed nitrogen can be introduced directly into organic compounds. Various cyclohexenone derivatives 9 were examined, and enol triflate gave a good result. When CsF was added to this solution as an additive, the yields increased (runs 2 and 4). Provably, CsF would accelerate the cleavage of the nitrogen-silicon bond on titanium-nitrogen complexes. To clarify whether N(TMS)3 in titanium-nitrogen complexes 7a is an active species, the reaction of 9a with N(TMS)₃ was carried out in the presence of CsF.

However, no product containing nitrogen was formed, indicating that the nitrogen source of **10** is derived from a titaniTable 2. Synthesis of Heterocycles

um–nitride complex or a titanium–amide complex. Thus, we next attempted to synthesize heterocycles from molecular nitrogen as a nitrogen source. Our plan is shown in Scheme 2. On the basis of the above results, if keto cyclohexenone I bearing a keto–carbonyl group in a tether at the 2-position is treated with titanium–nitrogen complexes **7a**, molecular nitrogen would be introduced at the 3-position of cyclohexenone, and then fixed nitrogen would further react with the carbonyl group in a tether to give cyclized compounds **II**.

We were very pleased to find that when a THF solution of **11a** and **7a** was refluxed overnight, indole derivative **12a** was obtained in 51% yield (Scheme 3, Table 3, run 1). In this reaction, the addition of CsF gave a good result (runs 2 or 3) and the hydroxy group was suitable as a leaving group (runs 3 and 5), although the reaction of **9h** with **7a** did not give a good result. Various indole derivatives were obtained in high yields. Elongation of the methylene group in a tether gave dihydroquinoline derivative **12f** in moderate yield. In this reaction, the spot on the TLC of the reaction mixture was different from that of the purified product **12f**. Presumably, tetrahydroquinoline derivative **13** would be formed, and then easily converted into dihydro-derivative **12f** by air oxidation. The treatment of triketone **11g** in a similar manner afforded **12f** in the same yield.

Synthesis of Pyrrole Derivatives from 1,4-Diketone. Since it was clear that titanium–nitrogen complexes 7a could react with the carbonyl group of I, we next tried to synthesize pyrrole derivative IV from 1,4-diketone III (Scheme 4). If 1,4diketone III were treated with titanium–nitrogen complexes 7, pyrrole derivative IV would be formed.

When compound 14a was treated with titanium-nitrogen

complexes **7a**, pyrrole derivative **15a** was obtained in 25% yield (Table 4, run 1). In a similar manner, various pyrroles **15b–e** (runs 2–5) or fuzed-pyrrole derivatives **15f–h** (runs 6–8) could be synthesized in good-to-moderate yields. The ester group of **14e** did not react with **7a** (run 5).

Synthesis of Pyrrolizine and Indolizine Derivatives. Since titanium–nitrogen complexes 7a could react with two keto–carbonyl groups to give pyrrole derivatives, we next examined the reaction of titanium–nitrogen complexes 7 with triketone V. If this reaction proceeds, it would be possible to synthesize pyrrolizine or indolizine derivatives VI in one step from triketone (Scheme 5).

To a THF solution of **7a** was added triketone **16a** and CsF, and the whole solution was refluxed overnight to give a mix-

ture of pyrrolizine derivatives (**17a**, **17b**, and **17c**) as an inseparable mixture in 31% yield, whose ratio was determined to be 1:1.8:1 by a ¹HNMR spectrum (Scheme 6). The hydrogenation of these compounds with PtO_2 in EtOH afforded pyrrolizine derivative **17c** in 86% yield. In a similar manner, **16b** gave the same pyrrolizine derivatives (**17a**, **17b**, and **17c**) in the same ratio in 32% yield.

A treatment of triketone 18 with 7a gave pyrrolizine derivative 19 in 30% yield (Table 5, run 1). Although the yield was moderate, it is very interesting that the pyrrolizine derivative 19 could be synthesized from triketone 18 and 7a by a one-step reaction. Triketone 20 was treated with 7a in a similar manner to give tricyclic compound 21 as a mixture of two inseparable isomers in 31% yield (run 2). Subsequently, the synthesis of an indolizidine derivative was examined. Triketone 22a, whose one methylene was elongated compared with that of 18, was treated with 7a to give indolizine derivative 23a in 29% yield. When 2 equiv. of 7a was used for this reaction, the yield of 23a increased to 41% (run 3). In a similar treatment of 22b, 22c, and 22d with 7a (2 equiv.), indolizine derivatives 23b, 23c, and 23d were formed in 56%, 30%, and 30% yields, respectively (runs 4–6). Synthesis of Heterocycles from Keto–Alkyne. Next, the Michael-type addition of titanium–nitrogen complexes 7 to α , β -unsaturated compound was examined. Our plan is shown in Scheme 7. A THF solution of keto–alkyne **24a** (1 equiv.) and titanium– nitrogen complexes **7a**, which was prepared from TiCl₄ (1.2 equiv.), Li (10 equiv.), and TMSCl (10 equiv.) under nitrogen, was refluxed in the presence of CsF (6 equiv.) for 17 h. Surprisingly, indole derivative **25a** was obtained in 90% yield (Scheme 8, Table 6, run 1). When the reaction was carried out at room temperature for 24 h, the desired indole derivative **25a** was obtained in 59% yield (run 2). On the other hand, when Ti(OⁱPr)₄ was used for the preparation of titanium–nitrogen complexes **7b** in a similar manner, the reaction proceeded at room temperature for only 50 min and **25a** was obtained in 82% yield (run 3). In the absence of CsF, the yield slightly decreased (run 4). Indole derivative **25b**, having an acetoxy group on a six-membered ring, was also synthesized from keto–alkyne **24b** (run 5). Subsequently, the effect of a substitu-

ent on alkyne was examined. In the case of the nitrile group, the yield was also high (run 6), and **24d** or **24e** bearing the amide or keto–carbonyl group on alkyne gave the desired indole derivative, **25d** or **25e**, in moderate yields (runs 7 and 8). Although, keto–alkyne **24f** having the alkyl group on an alkyne part gave only a trace amount of the desired product **25f** (run 9), keto–alkyne **24g** having a phenyl group afforded indole derivative **25g** in moderate yield (runs 9 and 10). These results indicate that the electron-withdrawing group on the alkyne gives a good result.

Thus, the substituent effect of the aromatic ring on the alkyne was examined (Scheme 9). The results are given in Table 7. The electron-withdrawing group on the aromatic ring gave good results (runs 2–4), but keto–alkyne **26e** having the

nitro group did not give the desire product (run 5). In the case of keto–alkyne **26f** having the methoxycarbonyl group at the ortho-position on the aromatic ring, small amounts of tetracyclic compounds **28** and **28'** were obtained (runs 6 and 7). Various mono- and bicyclic heterocycles were synthesized from keto–alkyne **29** using **7b** (Scheme 10), the results are given in Table 8. The desired heterocyclic compounds, such as pyrroles **30a** and **30b**, quinolines **30c**, and piperidine derivatives **30d** and **30e**, were obtained in good-to-moderate yields.

The possible reaction course for the formation of heterocyclic compounds from keto-alkyne is shown in Scheme 11. There are two possible pathways. If the reaction of keto-alkyne **24** with N(TMS)₃ proceeds in the presence of CsF, imine **i** would be formed. Then, a Michael addition of nitrogen of imine would afford **ii**, which would isomerize to give **25** (path A). However, when **24a** was reacted with N(TMS)₃ in the presence of CsF at room temperature for 16 h, no cyclized product was formed, indicating that N(TMS)₃ in titanium-nitrogen complexes **7b** is not an active species. Thus, the active species in this reaction would be a titanium-imide complex [XTi=N(TMS)] or titanium-amide complex [X₂Ti-

N(TMS)₂], and the complex would react with the carbonyl carbon to give imine **i** via **iii**.^{15,16} Then, the Michael addition of nitrogen gives **25**. The mechanism of this reaction is similar to that in the synthesis of a pyrrole derivative by Arcadi, who obtained a pyrrole derivative from keto–alkyne and primary amine.¹⁷ The total synthesis of (\pm) -pumiliotoxin C was achieved from **30g** (Fig. 2).¹²¹

Synthesis of Lactams from Keto-Carboxylic Acid. Next, we tried to synthesize lactam X from keto-carboxylic acid IX and 7 (Scheme 12). At first, a THF solution of acid chloride 31b and 7a, which was prepared using a TiCl₄-Li-TMSCl system under nitrogen, was refluxed in the presence of CsF to give lactam 32 in 28% yield (Scheme 13, Table 9, run 1). The use of titanium-nitrogen complexes 7b, prepared by a $Ti(O^{i}Pr)_{4}$ -Li-TMSCl system, slightly increased the yield of 32 (run 2). In this reaction, various carboxylic acid derivatives, such as chloride 31b, mixed anhydrides (31c and 31d, ester 31e), and even the carboxylic acid 31a, could be used and lactam 32 was produced in good yields (runs 1–7). Various bicyclic lactams (34, 36, and 38) were obtained in good yields using this method. In a similar manner, piperidone derivatives 40, 42, and 44 were also obtained in moderate yields from the corresponding keto-esters (39, 41, and 43).

Investigation of Titanium-Catalyzed Nitrogenation. As described in Scheme 1, this nitrogenation method was developed as a catalytic reaction based on a titanium complex. Although the reaction species are not clear, the possible reaction course is considered as shown in Fig. 3. TiX₄ would be reduced with Li and converted into TiX₂ **XI**, which would react with N₂ to give **XII**. This would then be converted into titanium-nitride complex **XIII** by Li and TMSCl and **XIII** would

react with TMSCl to give titanium–amide complex **XIV**. In the presence of Li, **XIV** reacts with TMSCl to give $N(TMS)_3$ and TiX₂ **XI** would be regenerated.

Thus, an experiment was carried out to determine whether nitrogen-heterocycles could be catalytically synthesized based on TiX₄ from molecular nitrogen (Scheme 14). To determine whether TiCl₄ acts as a catalyst, titanium–nitrogen complexes **7a** were synthesized from TiCl₄ (1 equiv.) in the presence of excess amounts of Li (50 equiv.) and TMSCl (50 equiv.) under an atmosphere of nitrogen. To this solution was added a THF solution of an excess amount of 1,3-diketone derivative **9a** (10 equiv.), and the solution was refluxed overnight. After the usual workup, enamide **10** was obtained in 189% yield based on TiCl₄. This means that TiCl₄ acts as a catalytic reagent in this

Scheme 13.

reaction. It was already reported that the reaction of **9a** with $N(TMS)_3$ did not afford **10**. However, in this reaction, the use of 1 equiv. of TiCl₄ in the presence of the excess amounts of Li and TMSCl afforded 189% yield of **10**. Although the reason why TiCl₄ acts as a catalytic reagent is not clear, the possibility for a catalytic reaction is that the titanium species acts as a Lewis acid in this reaction, or generated titanium-oxide

Subsequently, the synthesis of indole derivatives was carried out using a catalytic amount of TiX_4 (Scheme 15). The reaction procedure was similar to that used in the synthesis of **10**, the results are given in Table 10. In a similar manner, pyrrole derivatives were synthesized using a catalytic amount of $TiCl_4$, as shown in Table 11. In all cases, indole and pyrrole derivatives were obtained in more than 100% yield. These results mean that these heterocycles could be synthesized from molecular nitrogen as a nitrogen source using a catalytic amount of TiX_4 .

Conclusion

Nitrogen fixation is a very interesting and useful method for synthetic organic chemistry, and studies concerning for the utilization of molecular nitrogen in organic synthesis are exciting. It is known that various transition metals can fix nitrogen, but there have been few reports on the incorporation of nitrogen into organic compounds. We previously reported that the heterocycles could be synthesized using the titanium-nitrogen complex reported by Yamamoto. Next, we considered whether nitrogen can be catalytically introduced in regard to the metal. After various attempts had been made, a novel TiCl₄ or Ti(OⁱPr)₄-Li-TMSCl system was developed for nitrogen fixation, and it was found that the reaction proceeded catalytically based on TiX₄ in the presence of excess amounts of Li and TMSCl under nitrogen (1 atm). This method was then extended to the synthesis of heterocycles as a stoichiometric reaction, and various heterocycles, such as indole, quinoline, pyrrole, pyrrolizine, indolizine derivatives, and lactams, could be synthesized from molecular nitrogen as a nitrogen source. Furthermore, various heterocycles were obtained by a catalytic amount of titanium-nitrogen complexes in the presence of excess amounts of Li and TMSCI. The results mean that titanium-nitrogen complexes could be used as nitrogenation reagents for the synthesis of nitrogen containing compounds and heterocycles.

Experimental

All manipulations were performed under a nitrogen atmosphere using standard Schlenk techniques, and all of the reaction solutions were degassed through a freeze–pump–thaw cycle. THF and TMSCl were distilled under an argon atmosphere from so-dium diphenylketyl (THF) or CaH₂ (TMSCl). All other reagents and solvents were purified when necessary using standard procedures. Column chromatography was performed on silica gel 60 (70–230 mesh, 60 Å), and flash chromatography was performed on silica gel 60 (230–400 mesh, 60 Å) using the indicated solvent. The melting points are uncorrected.

Typical Procedure for Synthesis of Titanium–Nitrogen Complexes 7. To a suspension of Li (10 equiv.) in THF was added TiCl₄ or Ti($O^{i}Pr$)₄ (1 equiv.) and TMSCl (10 or 16 equiv.) at -78 °C, and the solution was degassed by a freeze–pump–thaw cycle. The atmosphere of the reaction vessel was changed to nitrogen, and the solution was stirred at room temperature under nitrogen (1 atm) overnight. The resultant black solution was used as titanium–nitrogen complexes 7.

General Procedure for the Synthesis of Nitrogen Heterocycles. To a black solution of 7 (1.25 equiv.) were added a substrate (1 equiv.) and CsF (6 equiv.); the solution was then stirred at an appropriate temperature. After cooling, water was added and the solution was stirred at room temperature until the black precipitate had disappeared. The aqueous solution was made basic by K_2CO_3 , and the solution was extracted with ethyl acetate. The organic layer was washed with brine, dried over Na₂SO₄, and concentrated. The residue was purified by column chromatography on silica gel to give a nitrogen-fixation product.
