Reactions between bis(trimethylsilyl)methyllithium LiCHR₂ and a nitrile R'CN gave lithium 1-azaallyls, β-diketiminates or 1,3-diazaallyls. The products of related processes involving the lithium alkyl LiCH₂R, LiCH(R)Ph or $[\text{Li}(\text{tmen})]_2[1,2-\{C(H)R\}_2C_6H_4]$ have also been obtained (R = SiMe₃ and R' = Bu^t, Ph or C_6H_4 Me-4). Analytical and spectroscopic data served to identify the following crystalline compounds: $[\text{Li}\{N(R)C(Bu^t)C(H)R\}(D)]_n$ [D absent and n = 2; D = tmen or dme and n = 1, $[\text{Li}\{N(R)C(Ph)C(H)R\}(D)]_n$ [D = tmen or pmdien and n = 1, or D = thf and n = 2], $[\text{Li}\{N(R)C(Ph)C(H)C(R'')NR\}(D)]_n$ [D absent, n = 2 and R'' = Ph (4a), C_6H_4Me-4 (4b) or Bu^t ; or D = tmen, $(thf)_2$ (9b), NEt₃ or thf and NCPh and n = 1 and R'' = Ph, $[Li\{N(R)C(Ph)C(H)C(Ph)NR\}(D)Li(CHR_2)]$ $[D = OEt_2 \text{ or thf}], [Li\{N(R)C(Ar)NC(Ph)=C(H)R\}(D)]_n [D = tmen, n = 1 \text{ and } Ar = Ph \text{ or } C_6H_4Me-4; \text{ or } D = thf, n = 2$ $and \ Ar = Ph], \\ [Li\{N(Ph)C(R)NC(Ph) = C(H)R\}(tmen)], \\ [Li\{N(R)C(Bu^t)CH_2]_2, \\ [Li\{N(R)C(Ph) = C(H)Ph\}(tmen)], \\ [Authorized]_2, \\ [Authorized]_3, \\ [Authorized]_4, \\ [Authorized]_4, \\ [Authorized]_4, \\ [Authorized]_6, \\ [Authorized]_6, \\ [Authorized]_7, \\ [Authorized]_8, \\ [$ [Li(tmen)]₂[1,2-{N(R)C(Bu^t)CH}₂C₆H₄]. Each of the three classes of ligands has a diversity of ligating possibilities, functioning towards lithium variously in a terminal or bridging and mono- or bi-dentate fashion, the role of a neutral donor D often being crucial. For an isomeric pair, the lithium β-diketiminate was thermodynamically preferred over the 1,3-diazaallyl. From [Li{N(R)C(But)C(H)R}]₂ and successively CH₂Br₂ and LiBun, the further lithium 1-azaallyl compound [Li{N(R)C(Bu^t)C(H)C(H)(R)Buⁿ}]₂ was obtained. From **4a** and CH₂Br₂ or (BrCH₂)₂ a bis(β-diketiminyl)-4b with successively KOBu^t and H₂O gave the β-diketimine HN(R)C(C₆H₄Me-4)C(H)C(C₆H₄Me-4)NR. Mechanistic pathways are proposed, which involve Me₃Si migrations: from C to N or N to N; or, for the latter a 1,2-dyotropic Me₃Si/H exchange. The crystal structures of eleven of these compounds have been determined. Each of the new lithium compounds may in principle behave as an N-, C-, (N,N')-, or (N,C)-centred nucleophile. Reactions demonstrative constant of the second se strating the first two alternatives for the β -diketiminate [Li $\{N(R)C(Ar)C(H)C(Ar)NR\}\}_2$ are (i) those with water $(Ar = C_6H_4Me-4)$ or $(BrCH_2)_2$ (Ar = Ph) which gave the diketimine N(R)C(Ar)C(H)C(Ar)N(H)R, whereas (ii) that with CH_2Br_2 (Ar = Ph) yielded $CH_2[C{C(Ph)NR}C(Ph)N(H)R]_2$.

Introduction

DOI: 10.1039/b002376k

In a series of communications we have shown that the interaction of a trimethylsilylmethyllithium reagent $\text{Li}[\text{CH}_{3-n}R_n]$ $(n=1, 2, \text{ or } 3 \text{ and } R = \text{SiMe}_3)$ and an α -hydrogen-free nitrile R'CN can yield a 1-azaallyl-, β -diketiminato- or 1,3-diazaallyl-lithium compound depending on n, the nature of R', the stoichiometry and the absence or presence of a neutral co-ligand. Furthermore, we have demonstrated that each of such ligands (illustrated below for the case of n=2 in the delocalised mode as **A**, **B** and **C**, respectively) has a diversity of ligating

possibilities, functioning in a terminal or bridging fashion. The 1-azaallyl may bind to the metal in a chelating (η^3 -1-azaallyl) or open chain (η^1 -1-azaallyl or enamido) mode.

We have used these lithium compounds as ligand transfer agents, generating 1-azaallyls, β -diketiminates or 1,3-diazaallyls of various metals [*e.g.* there are papers on derivatives of K,^{5,6} Cu^{I,7} Sn^{II,6} Hg^{II,6} and Au^{I 7b}]; this aspect,⁸ as well as the reaction pathways to Li(**A**), Li(**B**) and Li(**C**),⁹ have been reviewed. Some of the zirconium(IV) complexes, when treated with methyl-

aluminoxane ((MeAlO)_m, MAO), were effective catalysts for olefin polymerisation.⁹ Related chemistry has been based on the reactions of [Li{C(R)(R¹)(C₅H₄N-2)}]₂ or [Li{C(R)(R¹)-(C₉H₆N-2)}]₂ with R²CN; ¹⁰ some of the derived zirconium(IV) or hafnium(IV) complexes [M{N(R)C(R²)C(R¹)(C₅H₄N-2 or C₉H₆N-2)}_{4-m}Cl_m] were effective catalysts with MAO for the polymerisation of ethylene [R¹ = H or R (= SiMe₃), R² = Bu¹ or Ph and m = 1 or 2]. ¹¹ Further similar reactions were those between Li₂[η ⁵-C₅H₄Si(Me)₂C(H)R] and 2 Bu¹CN in the absence or presence of tmen. ¹²

The aim of this paper is to provide (i) full details of the material briefly described in the above mentioned communications, $^{1-4}$ (ii) extensions to related trimethylsilyl(methyl)lithium–R'CN systems, and (iii) details of the crystal structures of eleven representative lithium 1-azaallyls, β -diketiminates and 1,3-diazaallyls.

Compounds related to the lithium 1-azaallyls and β -diketiminates here reported, but prepared by different routes include the following: $[Li\{\eta^3\text{-}CH_2\text{=}C(Bu^t)NPh\}(OEt_2)]_2,^{13}$ $[Li\{2,6\text{-}[C(H)R]_2C_5H_3N\}Li]_1^{14}$ $[Li\{2\text{-}(CR_2)C_5H_4N\}(OEt_2)_n]_2$ (n=0 or $1),^{15}$ $[Li\{2\text{-}(CR_2)(C_5H_4N)\}(tmen)]_1^{15}$ $[Li\{2\text{-}(CR_2)(C_5H_4N)\}_1^{15}$ $[Li\{NC_5H_4|C(H)R_2|\text{-}2\}]_1^{15}$ $[Li\{2\text{-}(CR_2)(C_5H_3NMe\text{-}6)\}(tmen)]_1^{17}$ $[Li\{(C(H)R)(C_5H_3NCHR_2\text{-}6)\}(tmen)]_1^{17}$ $[Li\{N(H)\text{-}C(Bu^t)C\text{-}(H)Pr^n\}(hmpa)]_1^{18}$ $[Li\{(2\text{-}NC_5H_4)\text{-}CH_2\}(thf)_2]_1^{19}$ $[Li\{(2\text{-}NC_5H_4)\text{-}CH_2\}\}]_2^{19}$ and $[Li\{N(H)C(H)C(H)NH\}\{\mu\text{-}OP\text{-}(NMe_2)_3\}]_2^{20}$ The 1,3-diazaallyls presented in this paper belong

to the amidinates, a review of which, dealing with compounds such as the benzamidinate $[Li\{N(R)C(Ph)NR\}]_2$ is available.²¹

Results and discussion

The various reactions of LiCHR₂ (R = SiMe₃) with Bu^tCN and PhCN are summarised in Scheme 1. Treatment of LiCHR₂ with an equivalent portion of ButCN in Et2O or a hydrocarbon led (i in Scheme 1) in high yield to the 1:1 adduct, the lithium 1-azaallyl 1. Use of two equivalents of ButCN proceeded no further; affording the same product 1 after removal of solvents and heating the residue at 75 °C/10⁻² mmHg for 14 h. It is possible that a presumably unstable Lewis base adduct $1 \cdot n(NCBu^t)$ (n = 1 or 2), similar to **2a** and **2b**, had formed but dissociated at work-up. The tmen (2a) and dme (2b) adducts were, in contrast, much more stable and obtained (ii in Scheme 1) in high yield from 1 after addition of one equivalent of tmen or dme to 1 and subsequent recrystallisation from pentane. Treating 1 with the less bulky nitrile PhCN led (iii in Scheme 1) in a clean reaction to the lithium β-diketiminate 3.

The reaction of LiCHR₂ with PhCN is much more complex than that with ButCN. It was initially shown that treatment of these reagents at room temperature in Et₂O, independent of the ratio of LiCHR₂ to PhCN, gave (iv in Scheme 1) the lithium β-diketiminate 4. Using a 1:1 ratio of reagents, there was no evidence for the formation of a lithium 1-azaallyl (an analogue of 1) as an intermediate. Further investigation of this reaction showed that when it was performed in the presence of an excess of LiCHR₂ (1.5 fold to PhCN) at -78 °C in Et₂O, and the mixture worked up immediately after warming up to room temperature, the complex 5a, a co-crystal of LiCHR₂ and the lithium β-diketiminate 4a were obtained (v in Scheme 1) in moderate yield (45%), while the ¹H NMR spectrum of the mother liquor showed signals corresponding to a mixture of $LiCHR_2$ (as its Et_2O adduct) and $Li\{N(R)C(Ph)C(H)R\}$.

Although we have not been able to separate this mixture into its individual components, 5a was independently and conveniently produced (vi in Scheme 1) in satisfactory yield by dissolving LiCHR₂ and 4a in the presence of a slightly larger than stoichiometric amount of Et₂O; its thf analogue 5b was prepared from 5a by replacing the co-ordinated Et₂O with thf.

Although our attempts to isolate the solvent-free lithium 1-azaallyl Li $\{N(R)C(Ph)C(H)R\}$, by variation of reaction conditions or stoichiometry of the reactants, have not been successful, it was discovered that the reaction of LiCHR2 and PhCN in the presence of a stoichiometric amount of a neutral (chelating) electron donor such as tmen or pmdien led (vii in Scheme 1) in high yield to the donor-co-ordinated lithium 1-azaallyl complexes 6a and 6b. Use of the weaker electrondonor thf gave the corresponding thf complex 6c in a much lower yield (32%), with the lithium β -diketiminate **4a** as a co-product. When the same reaction was carried out in the presence of a large excess of thf (thf as solvent) and at higher temperature 6c was isolated in high yield (78%). Interestingly the reaction of **6a** with a second equivalent of PhCN gave not, as anticipated, the β -diketiminate 9a (a donor adduct of 4a) but instead (viii in Scheme 1) the lithium 1,3-diazaallyl 7a, which is a regioisomer of 9a. Treatment of 6a with 4-MeC₆H₄CN or PhNC gave the 1,3-diazaallyls 7c or 8, while reaction of LiCHR₂ with 2 equivalents of PhCN in thf gave 7b (viii, ix and xi, respectively in Scheme 1).

Investigation of the thermal stability of the 1,3-diazaallyl by heating a solution of compound 7b in toluene-d₈ in a sealed NMR tube showed that it was converted (x in Scheme 1) within 5 min at 100 °C into the isomeric diketiminate 9b, thus indicating that 9b is the thermodynamically more stable isomer. A wider range of β-diketiminates 9 was easily prepared (xii in Scheme 1) on a preparative scale from 4a by adding the appropriate neutral donor to the solvent-free compound 4, followed by recrystallisation from a hydrocarbon solvent.

The colourless (1, 2) or pale yellow (6) lithium 1-azaallyls were highly air-sensitive, extremely hydrocarbon-soluble compounds. The lithium 1,3-diazaallyls 7 and 8 and the lithium β-diketiminates 3, 4, 5 and 9 were, in contrast, yellow (3, 4, 7, 8, 9a, 9c, 9d), yellow-green (9b) or orange-red (5), but also soluble in hydrocarbons (except the solvent-free compounds 4 which were only moderately soluble) and slightly less air-sensitive than the 1-azaallyls.

The closely related lithium starting materials LiCH₂R, [Li(tmen)]₂[$\{1,2\text{-CH}(R)\}_2\text{C}_6\text{H}_4$] and Li $\{\text{CH}(R)\text{Ph}\}$ (tmen) behaved very similarly to LiCHR₂ with regard to their reactions with nitriles, as illustrated in eqns. (1)–(3) for the synthesis of the lithium-1-azaallyls 10–12. The outcome of reaction (4) lead-

$$2 \operatorname{LiCH_2(SiMe_3)} + 2 \operatorname{Bu^1CN} \longrightarrow [\operatorname{Li}\{N(R)C(\operatorname{Bu^1})\operatorname{CH_2}\}]_2 \ (1)$$

$$10$$

$$|\operatorname{Li}\{CH(\operatorname{SiMe_3})\operatorname{Ph}\}(\operatorname{tmen})| + \operatorname{PhCN} \longrightarrow [\operatorname{Li}\{N(R)\operatorname{C(Bu^1})\operatorname{CH_2}\}]_2 \ (2)$$

$$11$$

$$CH(R)\operatorname{Li}(\operatorname{tmen}) \longrightarrow [\operatorname{Li}\{\operatorname{CH}(\operatorname{SiMe_3})\operatorname{Ph}\}(\operatorname{tmen})] \longrightarrow [\operatorname{Li}\{\operatorname{CH}(\operatorname{SiMe_3})\operatorname{Ph}\}(\operatorname{tmen})] \longrightarrow [\operatorname{Li}\{\operatorname{CH}(\operatorname{SiMe_3})\operatorname{Ph}\}(\operatorname{tmen})] \longrightarrow [\operatorname{Li}\{\operatorname{CH}(\operatorname{SiMe_3})\operatorname{Ph}\}(\operatorname{tmen})] \longrightarrow [\operatorname{Li}\{\operatorname{CH}(\operatorname{SiMe_3})\operatorname{Ph}\}(\operatorname{CH})\operatorname{CH}] \longrightarrow [\operatorname{Li}(\operatorname{CH})\operatorname{CH}] \longrightarrow [\operatorname{Li}(\operatorname{CH})\operatorname{CH}]$$

ing to the 1-azaallyllithium complex 13 was unexpected. The purpose of adding CH_2Br_2 to compound 1 was to generate a methylene-bridged bis(1-azaallyl) precursor. Since a crystalline complex was not obtained, n-butyllithium was added, yielding 13 in modest yield.

The β -diketiminatolithium compounds **4a** (Ar = Ph) and **4b** (Ar = C₆H₄Me-4) generally behaved as *N*-centred (ii or iii in Scheme 2, or reactions with metal halides ^{1,8,9,13}) nucleophiles, but exceptionally (i in Scheme 2) functioned as *C*-centred reagents.

Scheme 2 Some reactions of the β -diketiminatolithium compounds 4a (Ar = Ph) and 4b (Ar = C_6H_4 Me-4) (R = $SiMe_3$).

Previously we suggested pathways to the lithium 1-azaallyl Li(**A**), β-diketiminate Li(**B**) and 1,3-diazaallyl Li(**C**) from LiCHR₂ and R'CN.⁸ Thus, the formation of Li(**A**) was attributed to initial nucleophilic attack of the ⁻CHR₂ carbanion at the nitrile carbon atom followed by a 1,3-Me₃Si shift from carbon to nitrogen. Li(**A**) was proposed to be an intermediate along the reaction path to Li(**B**) or Li(**C**), depending on whether Li(**A**) behaved as a *C*- or *N*-centred nucleophile, respectively; a final 1,3-Me₃Si migration from C to N for Li(**B**) or N to N for Li(**C**) completed the reaction sequence.

The major features of these proposals seem to us still to be persuasive. However, some new experimental observations have come to light which need to be accommodated. These relate to (i) the role of a neutral coligand D, (ii) different ligand-to-metal bonding modes of Li(A) and Li(A)D (see 2 or 6 in Scheme 1) and (iii) the isomerism of Li(B) and Li(C). As for (i), we draw attention to the contrast between steps iv $\{Ar = Ph \text{ yielding } [Li(B)]_2 \ 4\}$ and vii [giving Li(A)D 6] of Scheme 1. Regarding (iii), it is now evident (step x of Scheme 1) that the β -diketiminates (e.g. 9a) are the thermodynamically preferred isomers of the 1,3-diazaallyls (e.g. 7a). We now propose the modified reaction pathways summarised in Scheme 3. This shows the initial

formation of the donor–acceptor complex \mathbf{I} , leading to the 1,2-insertion product the imidolithium compound \mathbf{II} , which rearranges to the 1-azaallyllithium compound \mathbf{III} .

The formation of $[Li\{N(R)C(Bu^t)C(H)C(H)RBu^n\}]_2$ 13, from $[Li\{N(R)C(Bu^t)C(H)R\}]_2$ 1, according to eqn. (4), requires further comment. It is likely that compound 1 behaves as a C-centred nucleophile generating D, which with LiBuⁿ may first yield the dyotropic isomer E of 13. The use of the various lithium 1-azaallyls, β -diketiminates and 1,3-diazaallyls as ligand transfer reagents with metal halides will be reported in later papers (see also refs. 5–7). The role of the lithium 1-azallyl 1 in phosphorus chemistry, yielding diazaphosphetidines such as E or cyclic phosphonium salts such as E, has been described.

The 1-azallyl ligands are ambidentate nucleophiles; hence lithium derivatives are likely to exist in solution as a tautomeric mixture of a monomeric lithium iminoalkyl IIIa, a monomeric

lithium enamide IIIb and, in most cases in the absence of a neutral donor, a dimeric species IIIc. These three species are expected to be in equilibrium with one another. Dimeric species IIIc have been established for crystalline complexes 1 and 6c by single crystal X-ray diffraction studies. The lithium 1-azaallyl [Li $\{N(R)C(Ph)=CR_2\}(thf)$], related to 6c, was shown to be monomeric in the crystal and a low temperature ¹H NMR spectroscopic study provided no evidence for more than one species in solution. We suggest that IIIa is predominant in pentane or Et₂O solution at room temperature, since under these reaction conditions an excess of nitrile led to the formation of a β -diketiminate (3, 4, 5, or 9). Use of a chelating donor such as tmen or pmdien, or refluxing in thf as solvent, is likely to increase the abundance of IIIb; the presence of a powerful neutral donor increases the ionicity of the lithium 1-azaallyl and therefore favours structure IIIb, in which the more electronegative nitrogen atom is the anionic centre. As a consequence, a lithium 1,3-diazaallyl (7) is favoured in strongly polar solvents (thf > Et_2O) over an isomeric β -diketiminate (4 or 9). As mentioned above (item iii) the lithium 1,3-diazaallyl 7a was convertible into the thermodynamically more stable β -diketiminate 9a. This process was very fast in toluene (conversion within 5 min at 100 °C) but much slower in thf (not fully completed after 1 week at 65 °C) and involves, we believe, an equilibrium between 7, IIIb, IIIa and 4. A cross-over experiment, in which a mixture of 7a and 7c was heated in toluene, was inconclusive; slow decomposition of the sample occurred and a mixture of unidentified products was obtained and not, as expected, a mixture of lithium β-diketiminates.

In a series of additional experiments LiCHR₂ was treated with PhCN (2 equivalents) in thf, varying both reaction time and temperature (Table 1). After a selected reaction time the solvent was removed and the residue analysed by NMR spectroscopy and shown to be a mixture of the lithium 1,3diazaallyl 7b and β-diketiminate 9b. These results appear to contradict the earlier discussed notion of 9b being thermodynamically more stable than 7b, because the proportion of 7b to 9b increased with increasing temperature. A possible explanation is that there is a higher proportion of the dimeric species **IIIc** at lower temperatures, and that due to steric shielding of the nitrogen atoms **IIIc** behaves more as a C- than a N-centred nucleophile and therefore facilitates the formation of the lithium β -diketiminate 9b. At higher temperature, on the other hand, the abundance of the monomer IIIb is increased, which behaving as a N-centred nucleophile affords 7b. Refluxing for a longer period, or heating to a higher temperature, shifts the equilibrium back to 9b.

Olefinic proton or carbon

NMR Spectroscopy

The NMR spectroscopic data on compounds 1–12 are summarised in Table 2. Use of ⁷Li NMR spectroscopy provided a powerful tool for distinguishing between lithium 1-azaallyls $(\delta - 0.6 \text{ to } 0.9)$, lithium 1,3-diazaallyls (δ 1.6–1.9) and lithium β-diketiminates (δ 2.3–2.8) as the principal products of the reaction of LiCHR₂ with nitriles. Further help in the identification of the products came from ¹H NMR spectra, which showed characteristic, with the exception of compounds 11 and 12 (these have a very different backbone compared to the other compounds), resonances for the protons of the CH groups in the region of δ 3.5–4.5 (1-azaallyl), 4.4–4.7 (1,3-diazaallyl) and 5.1-5.9 (β-diketiminate). Additional support for the identification of a compound was provided by the ¹³C NMR spectra; the lithium 1-azaallyls showed shift values at δ 85–96 (CH) and 175–186 (CN), as compared to values close to δ 105 (CH) and δ 175 (CN) in lithium 1,3-diazaallyls or β -diketiminates. A distinction between the latter two isomeric compounds was easily accomplished on the basis of the lower molecular symmetry of the former, which gave rise to two distinct CN signals (and also two for the Me₃Si groups), as compared with one signal for the B-diketiminates.

In order to establish the structures of the above twentythree crystalline lithium complexes more securely, single crystal X-ray diffraction studies were undertaken on eleven representative samples: 1, 3, 4a, 5b, 6c, 7b, 8, 9a, 9b, 11 and 13. The molecular structures of 1,2 4a1 and 5b3 were described in preliminary communications. We now present such data on the remaining eight complexes, discuss trends and comment on bonding modes. Such problems have previously been discussed in the context of complexes of 1-azaallyls 7,23 or 1,3-diazaallyls 6 with other metals (Au^I, ^{7b} Sn^{II}, ^{6,23} Cu^I, ⁷ K⁶ and Hg^{II} ⁶).

to the latter class. They differ in that 7b is dinuclear, while 8 is mononuclear. Although in both the 1,3-diazaallyl ligand is bidentate and the LiNCN core is planar (8) or almost planar (7b), in 8 it is chelating whereas in 7b it is bridging. The molecular structure of 7b may be compared with those of five other dinuclear amidinates $[\text{Li}\{N(R)C(C_6H_4\text{Me-4})NR\}(thf)_2]$ H,²⁴ $[Li\{N(R)C(Ph)NR\}(NCC_{6}H_{4}Me\text{-}4)]_{2} \quad I,^{25} \quad [Li\{N(Ph)C(Ph)N-Ph\}(NCC_{6}H_{4}Me\text{-}4)]_{2} \quad I,^{25} \quad [N(Ph)C(Ph)N-Ph](NCC_{6}H_{4}Me\text{-}4)]_{2} \quad I,^{25} \quad [N(Ph)C(Ph)N-Ph](NCC_{6}H_{4}Me\text{-}4)]_{3} \quad I,^{25} \quad [N(Ph)C(Ph)N-Ph](NCC_{6}H_{4}Me\text{-}4)]_{4} \quad I,^{25} \quad [N(Ph)C(Ph)N-Ph](NCC_{6}H_{4}Me\text{-}4)]_{5} \quad [N(Ph)C(Ph)N-Ph]_{5} \quad [N(Ph)C(Ph)N-Ph]_{5} \quad [N(Ph)C(Ph)N-Ph]_{5} \quad [N(Ph)C(Ph)N-Ph]_{5} \quad [N(Ph)C(Ph)N-Ph]_{5} \quad [N(Ph)C(Ph)$ $(Ph)\}\{OP(NMe_2)_3\}]_2 J_{,26} [Li\{N(C_6H_4Me-4)C(H)NC_6H_4Me-4\} (OEt)_{2}_{2}_{1}$ K²⁷ and $[Li{N(Ph)C(Me)NPh}{\mu-OP(NMe_{2})_{3}}]_{2}$ L²⁶ which like 7b have an additional neutral ligand at each lithium atom; that of 8 is related to those of the mononuclear lithium amidinates $[Li{N(Ph)C(Ph)NPh}(tmen)]$ M^{27} and $[Li{N(Ph)C(Ph)NPh}(pmdien)]$ N.²⁶ In each of H-N each NCNLi core is planar.

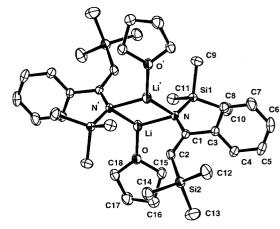

Fig. 3 Molecular structure of compound 6c.

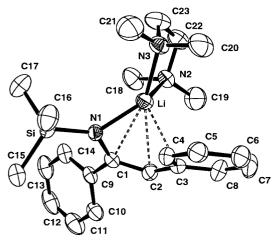

Complex 7b is a centrosymmetric dimer. Each anionic ligand is bound to the two lithium atoms in a bridging manner. Although this is also the case for H-K (in L it is simply a chelate), 7b is unique in having no close Li... N contact to a third nitrogen atom: Li-N(1) 1.989(11), Li-N(2) 1.985(11) and $Li \cdots N'$ 3.26(1) Å. In contrast, the third shortest $Li \cdots N$ contact in **H–K** is 2.145(8), 2.260(9), 2.137(7) and 2.231(9) Å, respectively. The mean of the two shorter Li–N contacts in 7b is 1.99(1) Å compared with 2.05(1), 2.06(1), 2.05(1) and 2.06(1) Å in H-K, respectively. The core in 7b is an eight-membered (LiNCN)₂ ring in chair conformation. Each of the lithium, nitrogen, oxygen and endocyclic carbon atoms is in a distorted trigonal planar environment, the distortion being minimal at carbon. The widest angle at each lithium atom is that subtended by the two neighbouring nitrogen atoms, while the C-N-Li and C-O-C angles are the narrowest at the nitrogen or oxygen atoms, respectively.

In the mononuclear crystalline complex 8 the geometric parameters of the chelating LiNCN core are very similar to those found in M^{27} or N^{26} Thus, the mean Li–N [2.014(9) Å] and C-N [1.367(6) Å] bond lengths are close to the 2.02(1) (**M**) or 2.13(11) Å (N) and 1.33(1) Å (M and N); cf. 28 also the mean Li-N distance of 2.04 Å in the LiNC(sp²)N unit of [Li{NC₅-H₃(NR)Me-2,6}(tmen)]. The angles subtended at Li, N (mean) and C are 67.5(3), 89.5(5) and 132.2(9)° for **8**, 67.6(2), 88.7(2) and 115.1(2)° for M, 27 and 64.4(2), 89.4(2) and 116.7(3)° for N. 26

A comparison between the NCN fragments of the LiNCN unit of compounds 7b and 8 shows there to be (i) a significant contraction from the C_{sp^2} value of the angle subtended at the carbon atom only for the mononuclear complex 8 [113.2(4)°], attributable to the chelate effect, and (ii) a more pronounced similarity in the two C-N distances for 8 (they are identical for \mathbf{M}^{27} and \mathbf{N}^{26}) than **7b**: $\Delta r = 0.029(6)$ Å for **8** and 0.062(7) Å for 7b. In respect of (ii), 7b also differs from the other binuclear complexes H-L. We conclude that 7b is unique in containing the shortest [1.302(7) Å] and to a less marked extent the longest [1.364(7) Å] C–N bonds among this family of nine lithium 1,3 diazaallyls and hence the least degree of NCN π -electron delocalisation. These data may be compared with the single and double NC bonds lengths in the bis(hydrogen-bonded) dimer [HN(Ph)C(Ph)NPh]₂ of 1.369(8) and 1.310(8) Å, respectively.²⁹

1-Azaallyls [Li{N(R)C(But)CHR}], 1, [Li{N(R)C(Ph)CHR}- $(thf)]_2$ $[Li\{N(R)C(Ph)C(H)Ph\}(tmen)]$ 6c. $[Li{N(R)C(Bu^t)CH(R)Bu^n}]_2$ 13. The molecular structure of complex 1² is shown schematically while those of 6c, 11 and 13 are illustrated in Figs. 3–5, respectively. Selected bond distances and angles are listed in Table 4.

The crystal structures of three lithium 1-azaallyls [Li{N-
$$\begin{split} &(Ph)C(Bu^{t})CH_{2}\}(OEt_{2})]_{2}\ \ \mathbf{O},^{13}\ \ [Li\{N(Ph)(C(=CH[CH_{2}]_{3}CH_{2})\}-(NHPr_{2}{}^{i})]_{2}\ \ P^{30}\ \ and\ \ [Li\{N(R)C(Bu^{t})CH_{2}\}]_{3}\ \ Q^{31}\ \ have\ \ previously \end{split}$$

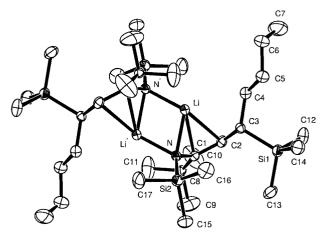

Molecular structure of compound 11. Fig. 4

been published and brief reference has been made to two others: the tetranuclear complex \mathbf{R}^{12} obtained from [Li $\{\eta$ -C₅H₄Si(Me)₂C(H)R}(tmen)]₂ and 2 Bu^tCN, and S.¹⁰ Closely related compounds are the 2-pyridylmethyls, ^{14,17,32} pioneered by Raston and exemplified by T and U.32a They differ from the 1-azaallyls in that, unlike in the latter, the pyridyl nitrogen atom cannot bear a negative charge unless the ring loses its aromaticity, which almost invariably is not the case. Thus, the relationship of the 1-azaallyls to the 2-pyridylmethyls is analogous to that of allyls to benzyls.

The molecular structures of the dinuclear compounds 1, 6c and 13 resemble one another and also those of \mathbf{O}^{13} and $\mathbf{P},^{30}$ in that each is a centrosymmetric dimer containing as core a nearly planar LiNLiN ring, with the angles subtended at the nitrogen atoms narrower [73.0(4) (1), 74.1(1) (6c) and 72.7(4)° (13)] than those at the Li atoms [107.5(5) (1), 106.0(1) (6c) and 107.3(4)° (13)]. The Li–N distances are closely similar {2.00(1) and 2.04(1) Å (1), 2.051(3) and 2.063(3) Å (6c), 1.983(9) and 2.035(9) Å (13), 2.00(1) and 2.08(1) (O)¹³ and 2.01(2) and

Molecular structure of compound 13.

2.08(2) Å (P) ³⁰]. Whereas 1 and 13 are free of neutral coligands, each of the remainder has a single such molecule at each lithium atom. Complexes 1 and 13 have Li-C_a and Li-C_b distances which are within bonding range [2.43(1) and 2.32(1) (1), 2.36(1) and 2.27(1) Å (13)]; consequently 1 and 13 are formulated as η^3 -1-azaallyllithium compounds. By contrast, complexes 6c, O 13 and P, 30 which contain a neutral coligand at each lithium atom, have appreciably longer Li–C $_{\alpha}$ and Li–C $_{\beta}$ contacts [3.01(1) and 2.62(1) (6c) and 2.99(2) and 2.57(1) Å (O)]; hence these are assigned as lithium enamides, i.e. η^{1} -1azaallyllithium complexes.

The molecular structures of the two mononuclear lithium compounds differ in that 11 is an enamide, whereas S is an η^3 -1azallyl, as evident from the Li– C_{α} and Li– C_{β} distances: 2.81(4) and 2.77(4) (11) and 2.23(2) and 2.32(2) Å (S)4 Å. In both complexes the Li-N distances are rather short: 1.97(4) (11) and 1.93(2) (S) Å. For 11 this is particularly noteworthy since its lithium atom is more co-ordinatively saturated than that in S, having not only a bidentate coligand (tmen; cf. thf in S) but also short Li-C contacts to the *ipso*-[2.77(4) Å] and *ortho*-[2.56(4) Å] carbon atoms of the phenyl substituent of C_a .

The C-C and N-C bond distances of the 1-azaallyl ligands in these complexes (see Table 4) do not appear to be diagnostic as to the nature of their bonding mode.

 β -Diketiminates [Li{N(R)C(Ph)C(H)C(Bu^t)NR}]₂ 3, $[Li{N(R)C(Ph)C(H)C(Ph)NR}]_2 4a$ [Li{N(R)C(Ph)C(H)C(Ph)NR}(LiCHR₂)(thf)] 5b, [Li{N(R)C(Ph)C(H)C(Ph)NR}(tmen)] 9a and

[Li{N(R)C(Ph)C(H)C(Ph)NR}(thf)₂] 9b. The molecular structures of complexes 4a¹ and 5b³ are shown schematically while those of 3, 9a, and 9b are illustrated in Figs. 6-8. Important bond distances and angles are summarised in Table 5.

The crystal structure of a lithium β -diketiminate [Li{N- $(Ph)(CH)_3NPh\}(\mu-OP(NMe_2)_3\}]_2$ V has been published.²⁰ The

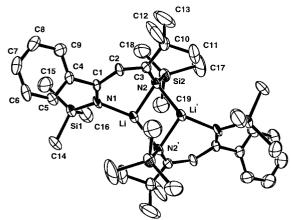

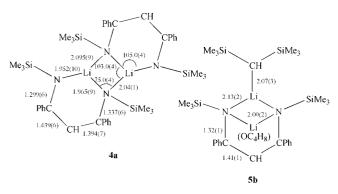

Fig. 6 Molecular structure of compound 3.

bis(2-pyridyl)methyllithium compounds [Li{(2-NC $_5$ H $_4$) $_2$ CH}-(thf) $_2$] **W**, [Li{(2-NC $_5$ H $_4$) $_2$ CH}{(2-NC $_5$ H $_4$) $_2$ CH} $_3$] **X** and [Li{(2-NC $_5$ H $_4$) $_2$ CH} $_2$] **Y** ¹⁹ are closely related to lithium 1-azaallyls, while the complexes obtained from PhCN or Bu^tCN and an appropriate 2-pyridylmethyllithium precursor ¹⁰ are similarly related to lithium β -diketiminates.

The dinuclear complexes **3** and **4a**¹ differ only in the substituents (Ph, Bu^t in **3**, but Ph, Ph in **4a**) at the C(N) atoms. Each molecule is a centrosymmetric dimer built around a planar LiNLiN core, the angle at the lithium atom being wider [103.8(7) (3) and 105.0(4)° (**4a**)] than that at nitrogen [76.2(6) (3) and 75.0(4)° (**4a**)]. One of the nitrogen atoms is four-coordinate and bridging, the other is three-co-ordinate. The intramolecular Li–N_{sp³} bond is slightly shorter [2.004(2) (3) and 1.965(9) Å (**4a**)] than the intermolecular Li–N_{sp³} [2.17(2) (3) and 2.095(9) Å (**4a**)]. The β-diketiminato ligand has a marginally

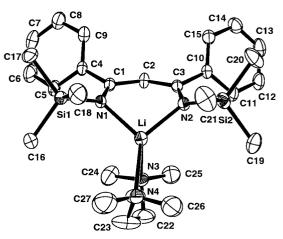

Fig. 7 Molecular structure of compound 9a.

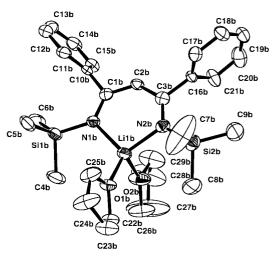

Fig. 8 Molecular structure of compound 9b.

shorter Li–N_{sp²} bond [1.973(15) Å (3) and 1.952(10) Å (4a)]. Within the LiNCCCN ring, the NCCC fragment is planar and there is some degree of π -electron delocalisation, although the pairs of N–C [1.271(11) and 1.333(11) Å (3) and 1.299(6) and 1.337(6) Å (4a)] and C–C bonds [1.460(11) and 1.415(11) Å (3) and 1.439(6) and 1.394(7) Å (4a)] are far from being identical. The lithium β-diketiminate V^{20} differs from 3 and 4a in that, although dinuclear, it has bridging hmpa ligands and thus it is

best considered with the mononuclear complexes. Complex $5b^3$ is distinct from 3, 4a and V in that it contains a single β -diketiminato ligand. Its skeleton is nearly planar and π -electron-delocalised. The two three-co-ordinate lithium atoms are on opposite sides of this plane; the Li–N distances are very similar.

The mononuclear complexes $\bf 9a$ and $\bf 9b$, like $\bf V$, 20 have a π -electron-delocalised and almost planar β -diketiminate skeleton, as evident by the essentially equivalent pairs of N–C [1.32(1) Å] and C–C [1.40(1) Å ($\bf 9a$), 1.39(1) and 1.42(1) Å ($\bf 9b$) and 1.39(1) Å ($\bf V$)] bonds. The four-co-ordinate lithium atom in each molecule is about 0.7 Å out of this plane and the Li–N $_{sp^2}$ distances are similar [2.02(1) Å in $\bf 9a$ and $\bf 9b$ and 2.04(2) Å in $\bf V$].

Experimental

General procedures

All manipulations were carried out under argon, using standard Schlenk techniques. Solvents were distilled from drying agents and degassed. The NMR spectra were recorded in C_6D_6 , C₆D₅CD₃ or CDCl₃ at 298 K using the following Bruker instruments DPX 300 (1H, 300.1; 13C, 75.5; 7Li, 116.6 MHz) and AMX 500 (1H, 500.1; 13C, 125.7; 7Li, 194.3 MHz) and referenced internally to residual solvent resonances (data in δ) in the case of ¹H and ¹³C spectra. The ⁷Li were referenced externally to LiCl. Unless otherwise stated all NMR spectra other than ¹H were proton-decoupled. Electron impact mass spectra were taken from solid samples using a Kratos MS 80 RF instrument. Melting points were recorded in sealed capillaries and are uncorrected. Elemental analyses (empirical formulae shown) were determined by Medac Ltd., Brunel University. In the experimental section, the abbreviation L for mass spectra denotes the ligand A, B or C.

Preparations

[Li{N(R)C(Bu')C(H)R}]₂ **1.** Method (i). Bu^tCN (0.40 cm³, 3.61 mmol) was added dropwise to a cooled (-20 °C) and stirred solution of LiCHR₂ (0.60 g, 3.61 mmol) in diethyl ether (ca. 15 cm³). The resultant solution was warmed to room temperature and stirred overnight. The solvent was removed in vacuo. The residue was dried at room temperature (10^{-2} Torr) for 1 h and extracted with pentane (ca. 20 cm³). The resultant extract was filtered. Concentrating the filtrate by slow evaporation of the solvent produced white crystals of compound **1** (0.98 g, 99%).

Method (*ii*). Bu^tCN (0.98 cm³, 8.87 mmol) was added dropwise to a cooled (-20 °C) and stirred solution of LiCHR₂ (0.74 g, 4.46 mmol) in diethyl ether (*ca.* 25 cm³). The mixture was warmed to room temperature and stirred for 14 h. The solvent was removed *in vacuo*; the residual solid was dried at 75 °C/ 10^{-2} Torr for 3 h and dissolved in hexane (*ca.* 15 cm³), filtering to remove an insoluble impurity. The filtrate was concentrated and set aside for a few days at room temperature to give white crystals of compound 1 (0.98 g, 89%), mp (decomp.) 145–148 °C (Found: C, 58.0; H, 11.61; N, 5.74. C₁₂H₂₈LiNSi₂ requires C, 55.6; H, 11.91; N, 5.90%); ¹H NMR ($C_6D_5CD_3$) δ 0.16, 0.24 (s, SiMe₃), 1.11 (s, CMe₃) and 4.47 (s, CH); ¹³C NMR ($C_6D_5CD_3$) δ 0.8, 4.8 (s, SiMe₃), 31.3 (s, C*Me*₃), 41.6 (s, *CMe*₃), 95.6 (s, CH) and 185.5 (s, CN).

[Li{N(R)C(Bu¹)C(H)R}(tmen)] 2a and [Li{N(R)C(Bu¹)C-(H)R}(dme)] 2b. Compounds 2a and 2b were obtained from LiCHR₂ and Bu¹CN as described for 1, except that reactions were carried out in C_5H_{12} with 1 equivalent of tmen or dme. Compound 1 (0.53 g, 2.12 mmol) and tmen (0.32 cm³, 2.12 mmol) gave 2a (0.71 g, 91.6%): 1H NMR (C_6D_6) δ 0.33 (s, SiMe₃), 0.47 (s, SiMe₃), 1.34 (s, Bu¹), 1.58 (m, NCH₂), 1.85 (s, NMe) and 4.02 (s, CH); 7Li NMR(C_6D_6) δ 0.34; ^{13}C NMR (C_6D_6) δ 1.8 (s, SiMe₃), 6.1 (s, SiMe₃), 31.2 (s, NMe), 40.6 (s, CMe₃), 46.1 (s, CMe₃), 56.4 (s, NCH₂), 83.4 (s, CH) and 185.6

(s, CN). Compound **2b**: mass spectrum m/z (%) 243 (20, [HL]⁺), 228 (43, [HL – Me]⁺) and 186 (79, [HL – Bu^t]⁺); ¹H NMR (C₆D₆) δ 0.32 (s, SiMe₃), 0.47 (s, SiMe₃), 1.34 (s, Bu^t), 2.60 (m, OCH₂), 2.96 (s, OMe) and 4.06 (s, CH); ⁷Li NMR(C₆D₆) δ –0.62; ¹³C NMR (C₆D₆) δ 1.1 (s, SiMe₃), 5.7 (s, SiMe₃), 31.0 (s, CMe₃), 40.6 (s, CMe₃), 59.4 (s, OMe), 69.6 (s, OCH₂), 83.6 (s, CH) and 184.8 (s, CN).

[Li{N(R)C(Bu')C(H)C(Ph)NR}]₂ 3. Benzonitrile (0.4 g, 5.09 mmol) was slowly added to a solution of [Li{N-(R)C(Bu')CH(R)}]₂ 1 (1.33 g, 2.05 mmol) in Et₂O (30 cm³) at *ca.* 25 °C. The resulting yellow solution was stirred for *ca.* 12 h. Volatiles were removed during 1 h at 90 °C/10⁻² Torr. Crystallisation from hexane afforded yellow crystals of complex 3 (1.40 g, 81%) (Found: C, 63.4, H, 9.50; N, 7.68. C₁₉H₃₃LiSi₂ requires C, 64.7; H, 9.43; N, 7.94%). ¹H NMR (360 MHz, C₆D₆) δ 0.03 and 0.04 (SiMe₃, s, 9 H), 1.25 (Bu^t, d, 9 H), 5.85 (CH, s, 1 H), 7.07–7.13 (phenyl, m, 3 H) and 7.37 (phenyl, d, 2 H).

[Li{N(R)C(Ph)C(H)C(Ph)NR}]₂ **4a.** PhCN (2.30 cm³, 22.53 mmol) was added slowly by syringe to a cooled (0 °C) and stirred solution of LiCHR₂ (1.85 g, 11.15 mmol) in diethyl ether (50 cm³). There was an immediate change from colourless to yellow. The resultant mixture was slowly warmed to room temperature and stirred for 2 h; the diethyl ether was removed *in vacuo*, and the resultant yellow-white solid heated to boiling, then cooled and filtered. The yellow precipitate was dried *in vacuo* and identified as compound **4a** (3.16 g, 76%), mp 167.5–171 °C (Found: C, 66.1; H, 8.32; N, 7.85. $C_{21}H_{29}LiN_2Si_2$ requires C, 67.7; H, 7.85; N, 7.52%); ¹H NMR ($C_6D_6-C_4D_8O$) δ –0.07, (s, SiMe₃), 5.49 (s, CH), 7.07–7.13 (m, Ph, 6 H) and 7.50–7.53 (m, Ph, 4 H); ¹³C NMR (C_6D_6) δ 3.0 (s, SiMe₃), 105.2 (s, CH), 127.4, 127.8, 127.9 (s, o, m, o-C of Ph), 149.8 (s, *ipso*-C) and 175.5 (CN).

[Li{N(R)C(C₆H₄Me-4)C(H)C(C₆H₄Me-4)NR}]₂ **4b.** Compound **4b** (1.09 g, 52%) (Found: C, 68.1; H, 8.66; N, 6.99. $C_{23}H_{35}LiN_2Si_2$ requires C, 69.0; H, 8.24; N, 7.00%) was prepared similarly, mp 188–191 °C. ¹H NMR ($C_6D_5CD_3$) δ 0.0 (s, SiMe₃), 2.07 (s, Me), 5.69 (s, CH), 6.93, 7.41 (d, Ph, 4 H). ¹³C NMR ($C_6D_5CD_3$) δ 3.0 (s, SiMe₃), 21.2 (s, Me) 106.9 (s, CH), 128.2, 128.6 (s, *m*, *p*-C of Ph), 137.7, 140.0 (s, *ipso*-C) and 176.5 (CN).

Reaction of LiCHR₂ with PhCN. A solution of PhCN (0.30 g, 2.88 mmol) in Et₂O (10 cm³) was added slowly to a solution of LiCHR₂ (0.72 g, 4.33 mmol) in Et₂O (30 cm³) at -80 °C. The resulting yellow solution was allowed to warm to room temperature and stirred for 90 min. The solvent was removed *in vacuo*, the residue "stripped" with pentane (this procedure refers to adding the solvent and then removing it *in vacuo*) and then dissolved in pentane (45 cm³). Filtration from a yellow precipitate (0.2 g) and cooling the filtrate gave yellow crystals of [Li{N(R)C(Ph)C(H)C(Ph)NR}]₂ **4a** (0.24 g, 44.7% based on PhCN). Concentration of the mother liquor yielded orange red crystals of compound **5a** (0.20 g, 23%), while further concentration gave colourless crystals which, according to ¹H NMR spectroscopic data, correspond to a mixture of LiCHR₂ and Li{N(R)C(Ph)C(H)R}.

[Li{N(R)C(Ph)C(H)C(Ph)NR}(LiCHR₂)(OEt₂)] 5a. Pentane (10 cm³) and Et₂O (0.1 cm³) were added to a mixture of solid [Li{N(R)C(Ph)C(H)C(Ph)NR}]₂ 4a (0.50 g, 0.67 mmol) and LiCHR₂ (0.22 g, 1.34 mmol). The resulting orange-red solution was concentrated. Cooling to -25 °C gave red crystals of compound 5a (0.47 g, 57%). From the mother liquor another 0.19 g (21.9%) was obtained, mp (decomp.) 129 °C (Found: C, 62.9; H, 9.48; N, 4.72. C₂₉H₆₅Li₂N₃OSi₄ requires C, 62.7; H, 9.54; N,

4.57%); ¹H NMR (C_6D_6) $\delta - 1.94$ (s, CHSi₂), 0.05 (s, NSiMe₃), 0.36 (s, SiMe₃), 0.92 [t, CH₃ (Et₂O), ${}^{3}J({}^{1}H-{}^{1}H)$ 7.1], 3.20 [q, CH₂ (Et_2O) , ${}^3J({}^1H-{}^1H)$ 7.1 Hz], 5.51 (s, CH), 7.03–7.14 (Ph, 6 H) and 7.44 (d, Ph, 4 H); 7 Li NMR (6 D₆) δ 2.3; 13 C NMR (6 D₆) δ 1.8 (s, CHSi₂), 3.0 (s, NSiMe₃), 5.7 (s, SiMe₃), 14.3 [s, CH₃ (Et₂O)], 65.9 [s, CH₂ (Et₂O)], 105.4 (s, CH), 127.4, 128.0, 128.8 (s, Ph), 148.0 (s, *ipso-C*) and 177.2 (s, CN).

 $[Li{N(R)C(Ph)C(H)C(Ph)NR}(LiCHR_2)(thf)]$ 5b. Compound 5a (0.3 g, 0.49 mmol) was dissolved in a mixture of pentane (8 cm³) and thf (0.1 cm³). Volatiles were completely removed in vacuo; the residue was treated with pentane (20 cm³). Filtration and concentration of the red filtrate gave upon cooling red crystals of compound 5b (0.1 g, 33%); ¹H NMR $(C_6D_6) \delta -1.90$ (s, CHSi₂), 0.05 (s, NSiMe₃), 0.396 (s, SiMe₃), 1.19 (m, thf), 3.40 (m, thf), 5.09 (s, CH), 7.09–7.12 (Ph, 6 H) and 7.48 (d, Ph, 4 H); $^7\text{Li NMR}$ (C₆D₆) δ 2.3; $^{13}\text{C NMR}$ (C₆D₆) δ 1.4 (s, CHSi₂), 2.8 (s, NSiMe₃), 5.9 (s, SiMe₃), 25.1 [s, CH₂ (thf)], 68.6 [s, OCH₂ (thf)], 105.4 (s, CH), 127.5–128.3 (s, Ph), 148.3 (s, *ipso-C*) and 176.8 (s, CN).

 $[Li\{N(R)C(Ph)=C(H)R\}(tmen)]$ 6a, $[Li\{N(R)C(Ph)=C(H)R\}$ (pmdien)] 6b and $[Li{N(R)C(Ph)=C(H)R}(thf)]_2$ 6c. The procedure for the preparation of each of compounds 6a-6c was very similar and is therefore reported in detail only for 6b. A solution of PhCN (0.31 cm³, 3.07 mmol) and pmdien (0.64 cm³, 3.07 cm³) in Et₂O (10 cm³) was added dropwise to a solution of LiCHR₂ (0.51 g, 3.07 mmol) in Et₂O (20 cm³). The mixture was allowed to warm to room temperature and stirred for 15 h. All volatiles were removed in vacuo and the residue was recrystallised from Et₂O to give colourless crystals of **6b** (1.23 g, 90%), mp (decomp.) 132 °C (Found: C, 61.6; H, 10.74; N, 12.47. C₂₃H₄₇LiN₄Si₂ requires C, 62.4; H, 10.74; N, 12.65%); mass spectrum m/z (%) 538 (75, $[LiL_2]^+$), 523 (20, $[LiL_2 - Me]^+$), 465 (10 $[LiL_2 - SiMe_3]^+$), 276 (100, $[Li_2L]^+$), 269 (56, [LiL]⁺), 262 (65, [L]⁺); ¹H NMR (C_6D_6) δ 0.08 (s, SiMe₃), 0.16 (s, SiMe₃), 1.74 (s, broad, NMe), 1.92 (s, NCH₂), 2.14 (s, NMe₂), 3.53 (s, CH), 7.15 (d, p-H of Ph), 7.24 [dt, m-H of Ph, $J(^{1}H-^{1}H)$ 6.8] and 7.57 [o-H of Ph, $J(^{1}H-^{1}H)$ 6.8 Hz]; ^{7}Li NMR(C₆D₆) δ 0.79; ¹³C NMR (C₆D₆) δ 3.1 (s, SiMe₃), 4.7 (s, SiMe₃), 45.6 (s, NMe), 45.9 (s, NMe₂), 53.9 (s, NCH₂), 57.1 (NCH₂), 84.1 (s, CH), 126.0 (s, p-C), 127.3, 129.7 (s, o/m-C), 150.7 (s, *ipso-C*) and 176.3 (s, CN).

Similarly, compound 6a (1.27 g, 85.6%) was obtained from LiCHR₂ (0.64 g, 3.85 mmol), PhCN (0.39 cm³, 3.85 mmol) and tmen (0.58 cm³, 3.85 mmol). It was recrystallised from pentane, mp (decomp.) 90 °C (Found: C, 60.9; H, 10.17; N, 11.48. C₂₀H₄₀LiN₃Si₂ requires C, 62.3; H, 10.45; N, 10.89%); mass spectrum m/z (%) 263 (40, [HL]⁺), 248 (10, [HL - Me]⁺), 186 (15, [HL – Ph]⁺) and 176 (50, [Me₃SiC=NPh]⁺); ¹H NMR $(C_6D_6) \delta 0.11$ (s, SiMe₃), 0.22 (s, SiMe₃), 1.55 (s, NCH₂), 1.79 (s, NCH₃), 3.67 (s, CH), 7.09–7.20 (Ph, 3 H) and 7.49 [dd, o-H of Ph, $J(^{1}H-^{1}H)$ 6.6 Hz]; ^{7}Li NMR($C_{6}D_{6}$) δ 0.88; ^{13}C NMR ($C_{6}D_{6}$) δ 2.6 (s, SiMe₃), 3.5 (s, SiMe₃), 45.5 (s, NCH₃), 56.2 (s, NCH₂), 83.1 (s, CH), 126.2–128.7 (s, o/m/p-C), 150.1 (s, ipso-C) and 175.9 (s, CN).

Likewise compound 6c (0.35 g, 31.5%) was obtained from LiCHR₂ (0.54 g, 3.25 mmol), PhCN (0.33 cm³, 3.25 mmol) and thf (0.52 cm³, 3.25 mmol) and was recrystallised from pentane; the second crop of crystals (0.44 g) consisted of a mixture of $Li\{N(R)C(Ph)C(H)R\}$ and **9b**. Compound **6c** was also prepared by addition of benzonitrile (2.9 cm³, 28.42 mmol) to a boiling solution of LiCHR₂ (4.95 g, 29.79 mmol) in thf (70 cm³) under reflux. The deep green mixture was stirred for 2 min and thf was removed in vacuo. The pale green residue was extracted into hexane (30 cm³). Cooling at -30 °C afforded pale yellow crystals of compound **6c** (7.95 g, 78%) (Found: C, 62.2; H, 9.35; N, 3.96. C₁₈H₃₂LiNOSi₂ requires C, 63.3; H, 9.44; N, 4.10%); ¹H NMR $(C_6D_6) \delta 0.04$ (s, SiMe₃, 9 H), 0.10 (s, NSiMe₃, 9 H), 1.36 (m, CH₂, 4 H), 3.69 (m, OCH₂, 4 H), 4.37 (s, CH), 7.10-7.17

(Ph, 3 H) and 7.40 [d, $J(^{1}H-^{1}H)$ 7.8 Hz, o-H of Ph, 2 H]. ^{7}Li NMR(C_6D_6) δ 0.76. ¹³C NMR (C_6D_6) δ 2.1 [s, SiMe₃], 3.9 (s, NSiMe₃), 25.4 (s, CH₂), 68.8 (s, OCH₂), 94.0 (s, CH), 127.0 (s, p-Ph), 127.6 and 128.9 (s, o- and m-Ph), 148.4 (s, ipso-C) and 174.7 ppm (s, CN).

 $[Li\{N(R)C(Ph)NC(Ph)=C(H)R\}(tmen)]$ 7a. A mixture of PhCN (0.39 cm³, 3.85 mmol) and tmen (0.58 cm³, 3.85 mmol) in Et₂O (10 cm³) was added dropwise to a solution of LiCHR₂ (0.64 g, 3.85 mmol) in Et₂O at -60 °C. The clear solution was warmed to room temperature and stirred for 15 h. The solvent was removed in vacuo; Et₂O (20 cm³) and PhCN (0.39 cm³, 3.85 mmol) were added and the solution stirred for 15 h. Removing the solvent and recrystallisation of the residue yielded pale yellow crystals of compound 7a (1.42 g, 86%), mp (decomp.) 110 °C (Found: C, 65.3; H, 9.08; N, 11.38. C₂₇H₄₅LiN₄Si₂ requires C, 66.3, H, 9.28, N, 11.46%); ¹H NMR (C_6D_6) δ -0.10 (s, SiMe₃), 0.13 (s, SiMe₃), 1.63 (s, NCH₂), 1.85 (s, NCH₃), 4.45 (s, CH), 7.05-7.19 (Ph, 6 H), 7.43 [dd, o-H of Ph, $J(^{1}H_{-}^{1}H)$ 8.1, 2 H], 7.51 [dd, o-H of Ph, $J(^{1}H_{-}^{1}H)$ 8.0 Hz]; $^{7}Li \text{ NMR}(C_{6}D_{6})$ δ 1.89; ¹³C NMR (C₆D₆) δ 1.2 (s, SiMe₃), 3.6 (s, SiMe₃), 45.3 (s, NCH₃), 56.2 (s, NCH₂), 108.2 (s, CH), 126.1-128.4 (s, Ph), 144.0, 147.2 (s, *ipso-C*), 164.2 (s, *C*=CH) and 175.0 (s, CN₂).

 $[Li{N(R)C(Ph)NC(Ph)}=C(H)R{(thf)}]_2$ 7b. Benzonitrile (2 cm³, 19.60 mmol) was added to a boiling solution of LiCHR₂ (1.37 g, 8.24 mmol) in thf (30 cm³) under reflux. The orange solution was stirred for 5 min and the volatiles were removed in vacuo. The residual yellow solid was dissolved in hexane (20 cm³); cooling at -30 °C afforded pale yellow crystals of compound 7b (1.14 g, 31%), mp 145 °C (Found: C, 66.8; H, 8.22; N, 6.29. $C_{25}H_{37}LiN_2OSi_2$ requires C, 67.5; H, 8.29; N, 6.30%); mass spectrum m/z (%) 366 (17, $[\frac{1}{2}M - Li - thf]^+$), 351 (4, $[\frac{1}{2}M - Li - thf - Me]^{+}$, 293 (19, $[\frac{1}{2}M - Li - thf - SiMe_{3}]^{+}$) and 263 (82 [½M – Li – thf – NSiMe₃ – Me]⁺); ¹H NMR $(C_6D_5CD_3) \delta -0.16$ (s, SiMe₃), 0.01 (s, NSiMe₃), 1.14 (m, CH₂, 4 H), 3.60 (m, OCH₂, 4 H), 4.67 (s, CH), 6.92–7.17 (Ph, 8 H) and 7.26 (d, Ph, $J(^{1}H_{-}^{1}H)$ 6.9 Hz, 2 H); ⁷Li NMR ($C_{6}D_{5}CD_{3}$) δ 1.62; ¹³C NMR (C₆D₅CD₃) δ 1.1 (s, SiMe₃), 3.2 (s, NSiMe₃), 25.8 (s, CH₂), 68.5 (s, OCH₂), 113.6 (s, CH), 119.5, 127.3, 127.7, 127.9, 128.2 and 129.0 (s, aromatic carbons), 143.3 (s, *ipso-C*), 145.3 (s, *ipso-C*), and 164.0, 176.2 (s, CN).

 $[\text{Li}\{N(R)C(C_6H_4\text{Me-4})NC(Ph)=C(H)R\}(tmen)]$ 7c. Toluonitrile (0.31 cm³, 2.6 mmol) was added at -30 °C to a solution of compound **6a** (1 g, 2.6 mmol) in Et₂O (30 cm³). The mixture was allowed to warm to room temperature and stirred for 12 h. The solvent was removed in vacuo, the residue extracted into pentane and the extract filtered. Concentration of the filtrate and cooling gave yellow crystals of compound 7c (0.79 g, 60%); ¹H NMR (C_6D_6) δ -0.10, 0.15 (s, SiMe₃), 1.65 (s, NCH₂), 1.86 (s, NCH₃), 2.14 (s, Me), 4.43 (s, CH), 6.98 [d, Ph, $J(^{1}H-^{1}H)$ 7.80, 2 H], 7.14 (m, Ph, 3 H), 7.36 [d, Ph, $J(^{1}H-^{1}H)$ 7.80] and 7.52 [d, Ph ${}^{3}J({}^{1}H-{}^{1}H)$ 6.68 Hz, 2 H]; ${}^{7}Li NMR(C_{6}D_{6}) \delta$ 1.90; ${}^{13}C$ NMR $(C_6D_6) \delta 1.2$, 3.7 (s, SiMe₃), 21.2 (s, Me), 45.4 (s, NCH₃), 56.3 (s, NCH₂), 107.9 (s, CH), 119.5 (s, *ipso-C*), 126.6, 127.3, 128.1, 129.1, 129.7 (s, o-, m-, p-C), 135.8, 141.2, 147.4 (s, ipso-C), 164.3 (s, C=CH) and 175.3 (s, CN₂).

 $[Li{N(Ph)C(R)NC(Ph)=C(H)R}(tmen)]$ 8. A solution of phenyl isocyanide (0.20 g, 2.0 mmol) in pentane (10 cm³) was slowly added to a solution of compound **6a** (0.77 g, 2.0 mmol) in pentane (30 cm³) at -78 °C. After stirring for 3 h at this temperature the reaction mixture was allowed to warm slowly to room temperature and stirred for 8 h. All volatiles were removed in vacuo and the residue was recrystallised from pentane or methylcyclohexane to give compound 8 (0.51 g, 52%), mp (decomp.) 98 °C; elemental analysis was unsatisfactory due to incorporation of solvent; mass spectrum m/z (%) 366 (42,

 $[HL]^+$), 351 (8, $[HL - Me]^+$), 293 (70, $[HL - SiMe_3]^+$), 191 (15, [(Ph)NC(SiMe₃)NH]⁺) and 176 (86, [Me₃SiC=NPh]⁺); ¹H NMR $(C_6D_6) \delta 0.24$ (s, SiMe₃), 0.45 (s, SiMe₃), 1.49 (s, NCH₂), 1.68 (s, NCH₃), 4.79 (s, CH), 6.95 [t, p-H of Ph, $J(^{1}H^{-1}H)$ 7.2, 1 H], 7.04 [d, o-H of Ph, $J(^{1}H_{-}^{1}H)$ 7.2], 7.17–7.29 (Ph, 5 H) and 7.72 [dd, o-H of Ph, $J(^{1}H-^{1}H)$ 6.8 Hz, 2 H]; $^{7}Li \text{ NMR}(C_{6}D_{6}) \delta$ 1.54; ¹³C NMR (C_6D_6) δ 1.9 (s, SiMe₃), 4.2 (s, SiMe₃), 45.0 (s, NCH₃), 56.2 (s, NCH₂), 96.7 (s, CH), 120.7, 123.2, 127.1, 127.3, 128.9, 129.4 (s, o/m-C of Ph), 119.4, 146.9 (s, ipso-C), 154.1 (s, C=CH) and 165.7 (s, CN₂).

 $[Li{N(R)C(Ph)C(H)C(Ph)N(R)}(tmen)]$ 9a. Addition of tmen (2 cm³, 1.3 mmol) to a stirred suspension of compound 4a (0.35 g, 0.47 mmol) in hexane (30 cm³) at ca. 25 °C immediately gave a clear solution. After stirring for 6 h this was concentrated to $ca. 3 \text{ cm}^3$. Cooling to $-30 \,^{\circ}\text{C}$ afforded the yellow crystalline compound 9a (0.4 g, 87%) (Found: C, 65.8; H, 9.09; N, 10.7. C₂₁H₂₉LiN₂Si₂ requires C, 66.3; H, 9.28; N, 11.5%); ¹H NMR $(C_6D_6)\delta - 0.12$ (s, SiMe₃), 1.90 (s, NCH₂, 4 H), 2.01 (s, NMe, 12 H), 5.57 (s, CH), 7.10–7.33 (m, Ph, 6 H) and 7.62–7.67 (m, Ph, 4 H); ²⁹Si NMR (C_6D_6) $\delta -6.7$, ¹³C NMR (C_6D_6) δ 3.9 (s, SiMe₃), 46.9 (s, NCH₂), 57.8 (s, NMe), 105.4 (s, CH), 127.4-127.8 (s, o-, m-, p-C of Ph), 150.0 (s, ipso-C) and 174.9 (s, CN).

[Li{N(R)C(Ph)C(H)C(Ph)NR}(thf)₂] 9b. From compound 4a (1.12 g, 3.01 mmol) in thf (20 cm³) at room temperature, using procedures similar to those for 9a, then recrystallisation from hexane, yellow-green crystals of compound **9b** (0.46 g, 30%) were obtained. When separated from the mother liquor these crystals lost thf rapidly. ¹H NMR ($C_6D_5CD_3$): δ -0.02 (s, NSiMe₃), 1.37 (m, CH₂, 8 H), 3.52 (m, OCH₂, 8 H), 5.34 (s, CH), 7.01-7.07 (Ph, 6 H) and 7.39 (Ph, 4 H). ⁷Li NMR $(C_6D_5CD_3) \delta 2.65$. ¹³C NMR $(C_6D_5CD_3) \delta 3.2$ (s, NSiMe₃), 25.7 (s, CH₂), 68.4 (s, OCH₂), 105.3 (s, CH), 127.5 (s, p-C of Ph), 128.3 and 129.2 (s, o- and m-Ph), 149.8 (s, ipso-C) and 175.7

[Li{N(R)C(Ph)C(H)C(Ph)N(R)}(thf)(NCPh)] 9c. Likewise, from compound 4a (1.0 g, 1.37 mmol) and PhCN (0.28 g, 2.7 mmol) in thf (50 cm³) at 25 °C, there was obtained, after recrystallisation from toluene, compound 9c (1.3 g, 90%). ¹H NMR ($C_6D_5CD_3$) δ 0.01 (s, SiMe₃₎, 1.34 (m, CH₂), 3.51 (m, OCH₂), 5.37 (s, CH), 6.60–7.15 (m, Ph, 9 H) and 7.43–7.50 (m, Ph, 6 H). 29 Si NMR ($C_6D_5CD_3$) $\delta - 5.7$ and 0.5. 13 C NMR $(C_6D_5CD_3) \delta 3.1$ (s, SiMe₃), 25.5 (s, CH₂), 68.2 (s, OMe), 105.2 (s, CH), 127.1–132.6 (s, o-, m-, p-C of Ph and C \equiv N), 149.8 (s, ipso-C), 170.5, 175.2 (s, CN).

 $Li\{N(R)C(Ph)C(Ph)N(R)\}(NEt_3)$ 9d. A mixture of $[Li{\{N(R)C(Ph)C(H)C(Ph)N(R)\}}]_2$ 4a (0.18 g, 0.24 mmol) and LiCHR₂ (0.08 g, 0.48 mmol) was dissolved in pentane (8 cm³) and $\overline{NEt_3}$ (0.05 cm³). After cooling to -25 °C, yellow crystals of **9d** (0.1 g, 43.7%) were obtained. ¹H NMR (C_6D_6) δ 0.08 (s, SiMe₃), 0.90 [t, CH₃, $J(^{1}H-^{1}H)$ 7.2], 2.52 [q, NCH₂, $J(^{1}H-^{1}H)$ 7.2 Hz], 5.60 (s, CH) and 7.10–7.13 (Ph, 6 H), 7.54 (d, o-H of Ph). ¹³C NMR (C_6D_6): δ 3.3 (s, SiMe₃), 10.4 (s, Me), 45.7 (s, NCH₂), 105.6 (s, CH), 127.6-128.7 (s, Ph), 149.1 (s, ipso-C) and 175.8 (s, CN).

 $[Li\{N(R)C(Bu^t)CH_2\}]_2$ 10. Bu^tCN (2.21 cm³, 20.0 mmol) was added dropwise to a stirred diethyl ether solution of LiCH₂R $(1.0 \text{ mol dm}^{-3}, 20 \text{ cm}^3)$ at $ca. 25 \,^{\circ}\text{C}$. The resulting solution was stirred for 12 h. Volatiles were removed during 1 h at 70 °C/10⁻² Torr. The residue was washed with pentane to give the white solid 10 (3.45 g, 97%) (Found: C, 58.6; H, 11.37; N, 7.33. $C_9H_{20}Li$ requires C, 61.0; H, 11.37; N, 7.90%); ¹H NMR (C_6D_6) δ 0.25 (s, SiMe₃), 1.15 (s, CMe₃), 3.80 (s, CH₂, 1 H), 4.48 (s, CH₂, 1 H) and 9.04 (m, Ph, 2 H).

[Li $\{N(R)C(Ph)=C(H)Ph\}\{tmen\}$] 11. PhCN (2.0 cm³, 20 mmol) was added by syringe to Li{CH(R)Ph}(tmen) (5.7 g, 19.93 mmol) in pentane (ca. 30 cm³) at ambient temperature. The mixture was stirred for 6 h. Filtration gave the yellow solid 11 (7.0 g, 90%) (Found: C, 70.8; H, 9.17; N, 10.26. C₂₃H₃₆LiN₃Si requires C, 70.9; H, 9.31; N, 10.79%); ¹H NMR (C_6D_6) δ 0.31 (s, SiMe₃), 1.41 (s, NCH₂), 1.68 (s, NMe), 5.53 (s, CH), 6.79 [t, Ph, 1 H], 7.11 (m, Ph, 4 H), 7.23 (d, Ph, 2 H) and 8.12 (m, Ph, 2 H).

 $[Li(tmen)]_2[\{1,2-N(R)C(Bu^t)C(H)\}_2C_6H_4]$ 12. Bu^tCN (1.39) cm³, 12.6 mmol) was added dropwise to a stirred solution of $[\text{Li}(\text{tmen})]_2[\{1,2\text{-CH}(R)\}_2C_6H_4]$ (3.1 g, 6.28 mmol) in Et₂O (ca. 40 cm³) at 25 °C. The resulting orange solution was stirred for 12 h. Volatiles were removed at 90 °C/10⁻² Torr, and the residue was extracted into hexane (ca. 50 cm³). The filtered extract upon concentrating yielded yellow crystals of complex 12 (3.1 g, 75%); ¹H NMR $(C_6D_6) \delta 0.54 \text{ (s, SiMe}_3)$, 1.53 (s, CMe₃), 1.69 (s, broad, tmen), 5.36 (s, CH), 6.92 (m, Ph, 2 H) and 9.04 (m, Ph, 2 H).

 $[Li{N(R)C(Bu^t)C(H)CH(R)Bu^n}]_2$ 13. Dibromomethane (0.45 cm³, 6.88 mmol) was added dropwise to a stirred solution of $[Li{N(R)C(Bu^t)C(H)(R)}]_2$ 1 (3.60 g, 6.88 mmol) in hexane (ca. 30 cm³) at 25 °C. The resulting suspension was stirred for 12 h and filtered. n-Butyllithium (1.6 mmol dm⁻³ in hexane, 7 cm³) was added to the filtrate at 25 °C; the solution was stirred for 4 h. Concentration yielded white crystals of compound 13 (0.60 g, 27%) (Found: C, 63.0; H, 11.78; N, 4.49. C₁₇H₃₈LiNSi₂ requires C, 64.1; H, 11.71; N, 4.40%); 1 H NMR (C₆D₆) δ 0.15 (s, SiMe₃), 0.33 (s, SiMe₃), 1.27 (s, CMe₃), 4.97 (d, CH), 0.92, 1.04 and 2.08 (Buⁿ).

 $CH_2[C\{C(Ph)NR\}C(Ph)N(H)R]_2$ 14. 1,2-Dibromoethane (0.34 g, 1.95 mmol) was added to a solution of $[Li{N(R)C(Ph)C(Ph)NR}]_2$ 4a (1.32 g, 1.77 mmol) in hexane (ca. 20 cm³). The mixture was refluxed for 10 h. The white precipitate of lithium bromide was filtered off. Concentrating the filtrate by slow evaporation of the solvent in vacuo gave yellow crystals of compound 14 (0.57 g, 43%), which were washed with hexane (ca. 5 cm³) and dried in vacuo, mp 193-198 °C (Found: C, 67.9; H, 8.44; N, 7.41. C₄₃H₆₀N₄Si₄ requires C, 69.3; H, 8.12; N, 7.52%); 1 H NMR (C₆D₅CD₃) δ 0.08 (s, SiMe₃), 2.65 (s, CH₂), 6.67 (d, Ph, 4 H), 7.01 (m, Ph, 6 H) and 11.80 (s, NH); 13 C NMR ($C_6D_5CD_3$) δ 2.0 (s, SiMe₃), 33.1 (s, CH₂), 110.5 (s, CH), 127.6, 128.4, 129.3 (s, o-, m-, p-C of Ph), 142.9 (s, ipso-C) and 170.1 (s, CN).

HN(R)C(Ph)C(H)C(Ph)NR 15a. BrCH₂CH₂Br (0.01 cm³, 0.82 mmol) was added by syringe to a solution of $K\{N(R)$ -C(Ph)C(H)C(Ph)NR} [prepared from 4a and KOBut (0.41 g, 1.01 mmol) in hexane (ca. 20 cm³)]. The mixture was maintained at 50 °C for 5 h. After filtration, the filtrate was concentrated in vacuo to yield yellow needles of compound 15a (0.36 g, 97%), mp 85–88 °C (Found: C, 68.9; H, 8.25; N, 7.82. $C_{21}H_{20}N_2Si_2$ requires C, 86.8; H, 8.25; N, 7.64%); ¹H NMR $(C_6D_6) \delta 0.04$ (s, SiMe₃), 5.39 (s, CH), 6.99 (m, Ph, 6 H), 7.21 (m, Ph, 4 H) and 12.38 (s, NH); 13 C NMR (C₆D₆) δ 1.9 (s, SiMe₃), 102.8 (s, CH), 127.4, 128.9, 132.8 (s, o-, m-, p-C of Ph), 143.7 (s, *ipso-C*) and 170.7 (s, CN).

 $HN(R)C(C_6H_4Me-4)C(H)C(C_6H_4Me-4)NR$ 15b. A suspension of $[\dot{L}i\{N(R)C(C_6H_4Me-4)C(H)C(C_6H_4Me-4)\dot{N}R\}]_2$ **4b** (0.33 g, 0.44 mmol) in hexane (ca. 10 cm³) was stirred under aerobic conditions until nearly all the solid had dissolved, changing from red to yellow. Slow evaporation of the solvent afforded yellow crystals of compound 15b (0.31 g, 96%), mp 120–124 °C (Found: C, 70.1; H, 9.17; N, 7.22. C₂₃H₃₄N₂Si₂ requires C, 70.0; H, 8.78; N, 7.10%); 1 H NMR (CDCl₃) δ 0.06 (s, SiMe₃), 2.39 (s, Me), 5.28 (s, CH) 7.16, 7.28 (d, Ph, 2 H) and

Crystal data and refinement details

Data were collected on an Enraf-Nonius CAD4 diffractometer using monochromatic Mo-K α or Cu-K α radiation [λ 0.71073 Å or 1.5418 Å (13)]. Crystals were either sealed in a Lindemann capillary under argon or else directly mounted on the diffractometer under a stream of cold nitrogen gas. Cell dimensions were calculated from the setting angles for 25 reflections with $7 < \theta < 10^{\circ}$. Intensities were measured by an ω –2 θ scan. Corrections were made for Lorentz and polarisation effects and in the case of compound 13 for absorption correction (DIFABS). The programs used for structure solutions and refinement were SHELXS 86 ³⁴ and SHELXL 93 ³⁵ (or MOLEN ³⁶). There was no crystal decay as measured by two standard reflections. Further details are found in Table 6.

CCDC reference number 186/2001.

See http://www.rsc.org/suppdata/dt/b0/b002376k/ for crystallographic files in .cif format.
