S Supporting Information

ABSTRACT: We report that the reductive cyclization of *o*-nitroarylamine with aldehyde using sodium dithionite (Na₂S₂O₄) could be accelerated by addition of H₂O, which made it possible to control the heat release of the reaction by semibatch-type operation. Safety evaluation was performed using DSC, ARSST, in situ IR analysis, and Multimax.

INTRODUCTION

Benzimidazole derivatives are important building blocks for inhibitors of hepatitis C virus (HCV) NSSB polymerase.¹ The discovery and preliminary SAR of the benzimidazole scaffold with a cyclohexyl or cyclopentyl ring at the *N*-1 position, a small aromatic or heteroaromatic ring at C-2 position, and a carboxylic acid function at C-5 position (e.g., *N*-1 cyclohexyl C-5 furyl compound **1**) were reported by Boehringer Ingelheim Inc.^{1a} Researchers at our company discovered that C-5 heteroaryl, *N*-1- and C-2-substituted benzimidazole compounds possess potency as inhibitors of HCV, and one of them was targeted for development as an active pharmaceutical ingredient (API) (Figure 1).^{1d}

In the medicinal chemistry route, benzimidazole building blocks were formed via hydrogenation of *o*-nitroarylamine and subsequent oxidative cyclization with aldehyde or the condensation with carboxylic acid and cyclodehydration (Scheme 1).

In order to simplify the steps, we attempted one-pot synthesis via reductive cyclization of *o*-nitroarylamine with aldehyde using sodium dithionite (Na₂S₂O₄) according to the literature to obtain benzimidazole **1** from commercially available ethyl 4-chloro-3-nitrobenzoate **2** on small scale (Scheme 2).²

The reaction could be an effective method for large-scale synthesis because Na₂S₂O₄ is inexpensive and easily available. However, there are known issues with regards to the scale-up of this type of chemistry. Reduction of the nitro group is very exothermic and compounds with the nitro group typically display violent and explosive decomposition.³ Also, accumulation of nitroso or hydroxylamine, which are intermediates of reduction of the nitro group, is dangerous, as these compounds are thermodynamically unstable. And explosion of Na₂S₂O₄, probably caused by contamination with water or oxidant, has been reported.⁴ It is therefore crucial to investigate how to control the reaction to avoid unexpected accidents. Herein, we report the examination of the reductive cyclization reaction with an aim toward plant-scale synthesis using ethyl 4-(cyclohexylamino)-3-nitrobenzoate **3** and benzaldehyde **6** as model compounds.

RESULTS AND DISCUSSION

Screening of Solvents and the Effect of H₂O. First, we screened the solvents by batch-type operation (Table 1). The reaction in ethanol (EtOH), isopropyl alcohol (IPA), and 2-butanol gave only the byproduct diamine **8** instead of benzimidazole **7**. However, the reaction did proceed on addition of

^a All reactions were performed using **3** (0.2 mmol), **6** (0.22 mmol), Na₂S₂O₄ (0.6 mmol) in solvent (0.5 mL). ^b All yields and conversions are calculated on the basis of HPLC analysis with an external standard. ^c Peak area % by HPLC analysis at 254 nm was shown.

Figure 2. Comparison of the conversion of *o*-nitroarylamine **3** in DMSO and DMSO/H₂O.⁵

H₂O, although the yields were moderate (entries 1–6). The reaction in DMSO gave benzimidazole **7** in high yield whether H₂O was added or not (entries 7 and 8). The reaction in other polar solvents such as DMA, DMF, and DMI gave moderate yields, which could be improved by adding H₂O (entries 9–14). The yield in DMSO/EtOH (1:1, v/v) was inferior to that in DMSO due to generation of byproduct **9** by completion of the decyclohexyl reaction (entry 15).

We compared the reaction rate in DMSO with that in DMSO/H₂O (10/1 = v/v) using in situ IR analysis. Addition of H₂O clearly accelerated the reaction (Figure 2). We finally chose DMSO/H₂O and DMA/H₂O as solvents for further examination.

DSC and ARSST experiments. We evaluated the reactivity of the reagents by differential scanning calorimeter (DSC) experiments to determine the explosive potential. A sealed SUS crucible was used, and a heating rate of 10 °C/min was applied. The results are shown in Table 2. *o*-Nitroarylamine **3**, Na₂S₂O₄ and the plausible byproduct NaHSO₃ exhibited exothermic decomposition of 1016, 480, and 69 J/g beginning at 317, 203, and 266 °C, respectively (entries 1, 4, and 5). On the other hand, benzaldehyde **6** and benzimidazole **7** did not show decomposition below 500 °C (entries 2 and 3). Next, we examined the stability of Na₂S₂O₄ in solvents because Na₂S₂O₄ contaminated by water is reported to be explosively exothermic.⁴ The decomposition onset temperature of Na₂S₂O₄ in DMSO or H₂O was lower than that of Na₂S₂O₄ (entries 6 and 7). The results suggest that these solvents could promote the decomposition of Na₂S₂O₄. On the other hand, Na₂S₂O₄ in DMA exhibited exothermic decomposition at the equivalent temperature of Na₂S₂O₄ (entry 8).

Next, we measured the thermal stability of the reaction mixture in DMSO/H₂O (10/1 = v/v) and DMA/H₂O (10/1 = v/v) using the Advanced Reactive Systems Screening Tool (ARSST). ARSST experiments were performed starting at 25 °C and heating the samples to 300 °C at the rate of 2 °C/min. The results are shown in Figure 3. The reaction mixture in both solvents did not show a dangerous exothermic peak although a moderate exothermic phenomenon beginning at 150 °C was observed on measurement of the reaction mixture in DMSO/H₂O.

Control of the Reductive Cyclization by Semibatch-Type Operation. We applied a semibatch process in which Na₂S₂O₄ (3 equiv) was added slowly to the mixture of 3 and 6 (1.1 equiv) dissolved in DMSO/H₂O or DMA/H₂O at 90 or 80 °C because Na₂S₂O₄ was the most thermally unstable reagent in the reaction. As the flash point of DMA (~70 °C) is lower than the reaction temperature, Na₂S₂O₄ should not be added as a powder, if possible, in order to avoid the generation of static electricity. We therefore measured the stability of Na₂S₂O₄ in H₂O at room temperature using in situ IR analysis. The result is shown in Figure 4. The solution was stable in nitrogen atmosphere but decomposed in air. The results suggest that Na₂S₂O₄ can be added as a mixture with excess H₂O under nitrogen atmosphere in a plant although Na₂S₂O₄ contaminated by H₂O is dangerous.

We measured the heat flow of the reaction using the operation shown below. A Multimax 250 vessel was charged with *o*-nitroarylamines 3 (6 g 20.5 mmol) and 1.1 equiv of benzaldehyde 6 in DMSO/H₂O and DMA/H₂O (10/1 = v/v 66 mL), and the mixture was heated to 90 and 80 °C, respectively. Next, 3.0 equiv of Na₂S₂O₄ was added over 90 min as powder because the addition of a Na₂S₂O₄ slurry in water under nitrogen atmosphere was difficult to perform in our laboratory. The reaction mixture was stirred for 2.5 h. The reactions respectively emitted heat of 797, 657 kJ/mol, and the respective adiabatic temperature rises were estimated to be 102 and 94 °C (Figures 5 and 6) (specific heat = 2 J/(g K)). The gross exothermic value was a little higher than the reported value of hydrogenation of nitrobenzene,^{3d} but the heat release was proportional to the rate of addition of Na₂S₂O₄, and the accumulation of thermally unstable nitroso or hydroxylamine was not observed by HPLC and in situ IR analysis. In the case of DMSO/H₂O, a large exothermic peak (~700 W/mol) was observed when half of the Na₂S₂O₄ was added, which was presumed to be the crystallization heat of salt according to the focused beam reflectance measurement (FBRM)

Figure 3. (a) ARSST data for DMSO/H₂O (10/1 = v/v). (b) ARSST data for DMA/H₂O (10/1 = v/v).⁶

data (Figure 7). In summary, both solvents can be used for large-scale synthesis, but considering that DMSO is known as a highly reactive solvent and can cause an unexpected explosion in the presence of impurities, such as transition metal catalysts,⁷ DMA/H₂O would be a better choice than DMSO/H₂O. The most important aspect for the safe operation of this reaction is that the Na₂S₂O₄ should not be contaminated with water.

Consideration of the mechanism. In the case of unsubstituted *o*-nitroarylamines, the reaction is presumed to be initiated by imine formation, which could promote reduction of the nitro group by the electronic effect.^{2a} In this case, however, iminium ion formation of 3 with 6 was not observed by in situ IR analysis, and the intermediate, detected at less than 2% by HPLC during the addition of Na₂S₂O₄, was supposed to be 10.⁸ Thus, the first step of the reaction should be reduction of the nitro group, which requires 2 equiv of H₂O. This may account for the acceleration effect of H₂O (Scheme 3).

CONCLUSION

We demonstrated that the reductive cyclization reaction was accelerated by the addition of H₂O and the heat release could be controlled by semibatch-type operation. Safety evaluation by DSC, ARSST, in situ IR analysis, and Multimax removed concerns about using Na₂S₂O₄ in DMSO/H₂O or DMA/H₂O. In conclusion, we were able to propose a safe one-pot synthesis of benzimidazole via reductive cyclization of *o*-nitroarylamines with aldehyde using Na₂S₂O₄.

EXPERIMENTAL SECTION

All reactions were run under a nitrogen atmosphere. Solvents and reagents were obtained from commercial sources and used without further purification.

^1H NMR and ^{13}C NMR spectra were recorded on a 300 MHz Varian FT spectrometer. HRMS were recorded on a JEOL JMS-SX/SX102A. LCMS were recorded on a Shimadzu LCMS2010EV. All in situ infrared spectra were collected using a Mettler Toledo

Figure 6. Heat flow of the semibatch-type operation of the reaction in $\text{DMA}/\text{H}_2\text{O}$.

ReactIR iC10 equipped with a 6 mm diameter Diamond ATR probe (DiComp). The heat flow of the reaction was measured by Mettler Toledo MultiMax250. DSC was measured using a Mettler Toledo SDC822e. The total chord length counts were obtained by Lasentec focused beam reflectance measurement (FBRM), i.e., real-time measurement, while the crystallization was taking place. The stability of reaction mixture was measured by Advanced Reactive Systems Screening Tool (ARSST) manufactured by Fauske and Associates.

1-Cyclohexyl-2-(furan-3-yl)-1H-benzo[d]imidazole-5-carboxylic Acid (1). A 200-mL round-bottomed flask was charged with ethyl 4-(cyclohexylamino)-3-nitrobenzoate (5 g), DMSO (25 mL), EtOH (25 mL), 3-furaldehyde (1.81 g), and $\text{Na}_2\text{S}_2\text{O}_4$ (8.93 g). The mixture was stirred at 90 °C for 2.5 h. The mixture was quenched with water (100 mL) and extracted with ethyl acetate (100 mL $\times$ 1, 200 mL $\times$ 1, 50 mL $\times$ 1). The combined organic layers were washed with water (50 mL $\times$ 3) and concentrated by rotary evaporation. The crude residue was dissolved in THF (20 mL) and MeOH (10 mL), and then LiOH (1.86 g) dissolved in H_2O (18.6 mL) was added. The mixture was stirred at 30 °C for 1 h, cooled to 0 °C, and adjusted to pH 4 with HCl(aq). The precipitate that formed was obtained by filtration, washed with H_2O (100 mL), and dried at 40 °C under reduced pressure to obtain the title compound (4.22 g, 80%). ^1H NMR (300 MHz, DMSO- d_6) δ 8.28 (1H, d, J = 0.6 Hz), 8.20 (1H, d, J = 1.8 Hz), 7.94–7.91 (2H, m), 7.83 (1H, dd, J = 8.7, 1.8 Hz), 6.94 (1H, d, J = 2.1 Hz), 4.48–4.39 (1H, m), 2.40–2.20 (2H, m), 2.00–1.80 (4H, m), 1.70–1.60 (1H, m), 1.50–1.30 (3H, m); ^{13}C NMR (300 MHz, DMSO- d_6) δ 168.5, 149.1, 145.2, 144.2, 143.7, 137.6, 125.2, 124.0, 121.7, 116.8, 113.6, 112.0, 57.6, 31.5, 26.5, 25.5; HRMS (FAB) m/z calc'd for $\text{C}_{22}\text{H}_{25}\text{N}_2\text{O}_2$ $[M]^+$: 311.1396, found 311.1394.

Ethyl 4-(Cyclohexylamino)-3-nitrobenzoate (3). A 1-L round-bottomed flask was charged with ethyl 4-chloro-3-nitrobenzoate (50.0 g), NMP (150 mL), cyclohexylamine (64.8 g), and triethylamine (66.0 g). The mixture was stirred at 90 °C for 1.5 h. The mixture was quenched by water (300 mL) and extracted by ethyl acetate (500 mL $\times$ 2). The combined organic layers were washed with water (300 mL), brine (300 mL), and water (300 mL) and concentrated by rotary evaporation. The residue was dried under reduced pressure at 40 °C to give 3 (63.3 g, 99%). This compound is already known, and the ^1H NMR data corresponded to the literature data.^{1d} ^1H NMR (300 MHz, CDCl_3): 8.86 (1H, d, J = 1.8 Hz), 8.35–8.46 (1H, m), 8.01 (1H, dd, J = 8.7, 1.5 Hz), 6.87 (1H, d, J = 9.3 Hz), 4.35 (2H, q, J = 7.2 Hz), 3.65–3.50 (1H, m), 2.14–1.29 (10H, m), 1.38 (3H, t, J = 7.1 Hz).

Ethyl 1-Cyclohexyl-2-phenyl-1H-benzo[d]imidazole-5-carboxylate (7). The reaction mixtures described in the

Results and Discussion section were cooled to room temperature, and then water was added to them. The resulting precipitate was obtained by filtration and washed with water, then purified by recrystallization from acetone and water to give benzimidazole 8 (87%, DMSO/ H_2O solvent; 86%, DMA/ H_2O solvent). ^1H NMR (300 MHz, CDCl_3) δ 8.51 (1H, d, J = 1.5 Hz), 7.98 (1H, dd, J = 9, 1.8 Hz), 7.62 (1H, s), 7.65–7.60 (2H, m), 7.56–7.25 (3H, m), 4.41 (2H, q, J = 7 Hz), 4.36–4.33 (1H, m), 2.40–2.20 (2H, m), 2.00–1.90 (4H, m), 1.42 (3H, t, J = 7.2 Hz), 1.40–1.28 (4H, m); ^{13}C NMR (300 MHz, CDCl_3) δ 166.9, 155.3, 143.2, 137.0, 130.5, 129.8, 129.3, 128.6, 124.3, 123.4, 122.3, 112.0, 60.8, 57.1, 31.4, 25.9, 25.3, 14.5; HRMS (FAB) m/z calc'd for $\text{C}_{22}\text{H}_{25}\text{N}_2\text{O}_2$ $[M]^+$: 349.1916, found 349.1923.

Ethyl 2-Phenyl-1H-benzo[d]imidazole-5-carboxylate (9). The title compound was isolated from the reaction mixture (entry 15, Table 2) by flash column chromatography on silica gel using hexane/ethylacetate (3:2) as the eluent to give 5.8 mg of 9 as a white solid. ^1H NMR (300 MHz, CDCl_3) δ 8.33 (1H, s), 8.18 (1H, dd, J = 7.8, 1.8 Hz), 7.93 (1H, dd, J = 8.4, 1.5 Hz), 7.54 (1H, d, J = 8.4 Hz), 7.25–7.40 (3H, m), 4.35 (2H, q, J = 7.2 Hz), 1.35 (3H, t, J = 7.1 Hz); ^{13}C NMR (300 MHz, CDCl_3) δ 167.2, 154.7, 130.4, 129.2, 128.9, 127.0, 124.6, 124.1, 61.0, 31.6, 22.6, 14.3, 14.2, 14.1; HRMS (FAB) m/z calc'd for $\text{C}_{16}\text{H}_{15}\text{N}_2\text{O}_2$ $[M]^+$: 267.1133, found 267.1141.
