### Abstract

Lipase mediated desymmetrization of a meso diol (1,2-cyclopentanedimethanol) allows the synthesis of both enantiomers of some chiral aldehydes, whose behaviour in Passerini and Ugi reactions has been explored. Exploiting these two complementary multicomponent reactions, and coupling them with a subsequent cyclization process, 6 out of all 8 possible stereoisomers of peptidomimetic pyrrolidines can be obtained in good yields. The potential of these protocols has been proved by the development of a new efficient synthesis of antiviral drug Telaprevir.

Isocyanide-based multicomponent reactions (IMCRs) have become very popular in recent years especially in the diversity-oriented synthesis<sup>1</sup> of libraries of drug candidates.<sup>2</sup> Although the advantages of high step- and atom-economy associated with these methodologies should make them also well suited to target-oriented synthesis, their exploitation in the total synthesis of Active Pharmaceutical Ingredients (APIs) has been much less explored,<sup>3-6</sup> probably because the literature reports typically deal with the synthesis of racemic substances from simple commercially available building blocks. The "real" drugs often call for chiral, enantiomerically pure, components, (wrongly) perceived too complex to be used in multicomponent chemistries. Biocatalysis<sup>7,8</sup> is a "green" and efficient methodology to prepare chiral building blocks. Our group has been active for nearly 30 years in this field and recently reported on the utilization of biocatalytically derived building blocks in diastereoselective isocyanide-based multicomponent reactions.<sup>9-11</sup>

In particular, monoesters **2** derived from desymmetrization<sup>7,8</sup> of *meso* or prochiral diols **1** are quite interesting, being convertible into aldehydes **3** and **5** (through the azide **4**) or into cyclic imines **6** (through intramolecular Staudinger-Aza-Wittig<sup>12</sup> reaction) (Scheme 1). In addition, the complementarity of enzymatic monoacylation / monohydrolysis and the intrinsic stereodivergency of these building blocks gives access to both enantiomeric series. Cyclic imines **6** have been subjected to Ugi-Joullié tricomponent reactions, which are often stereoconservative (proceeding with no epimerization) and diastereoselective.<sup>11,13</sup> On the other hand, the use of aldehydes **3** or **5** as starting component in IMCRs is unprecedented. We will therefore describe herein our latest results in this field, culminated in a new synthesis of important anti-viral drug Telaprevir.

### **Results and Discussion**

We chose as the *meso* diol for our studies the known cyclopentane derivative 7 (Scheme 2),<sup>14,15</sup> which was best prepared by reduction of *cis*-1,2-cyclopentanedicarboxylic anhydride.<sup>16-18</sup> From this diol we obtained in high e.e. both enantiomers of monoacetate **8** by using either an enzymatic acetylation or the complementary enzymatic monohydrolysis of the diacetate of **7**. After optimization, both enantiomers could be obtained in high enantiomeric excess (e.e.) (97% for **8** and 95% for *ent*-**8**). It is worth noting that, although both monohydrolysis<sup>19-21</sup> and monoacetylation<sup>20</sup> have been already reported with other enzymes, in our hands the e.e.s were not fully satisfactory and we had to test various enzymes and conditions before obtaining the best results. In particular, monoacetylation of **7** was best carried out by Amano PS lipase supported on Celite<sup>®</sup>.<sup>22</sup>

The following studies were carried out on the (1R,2S) isomer *ent*-8. Oxidation to the aldehyde *ent*-9 was carried out under Swern conditions. This aldehyde was found to be rather sensitive to epimerization and afforded the more stable *trans* isomer. However, by using *N*,*N*-di*iso*propylethylamine as the base and performing a rapid work-up at pH 4 (in order to remove all the base before evaporation) we were able to obtain diastereomerically pure *ent*-9. The stereochemical integrity was checked by BH<sub>3</sub> reduction followed by GC analysis. Due to this lability, the crude

aldehyde was directly submitted to a model Ugi reaction<sup>23,24</sup> with *n*-butyl isocyanide, propionic acid and *p*-methoxybenzylamine (PMB-NH<sub>2</sub>). The reaction proceeded in good yield, but with poor diastereoselectivity, affording a 1:1 mixture of the two diastereomers **10a,b**. We later demonstrated (after conversion into **12a,b**) that they were not the expected *cis* compounds, but the *trans* ones instead (a thorough discussion on the relative configuration is reported after discussion of the Passerini approach).

SCHEME 2. Ugi approach to trans-fused bicyclic pyrrolidines

Since only two diastereomers were detected, epimerization on carbon 6a (12a,b) was complete. We can rule out that the epimerization occurred during the oxidation, because the stereochemical integrity of *ent-9* was demonstrated by GC-MS analysis on the crude Swern product (after reduction to the corresponding alcohol by means of BH<sub>3</sub>) before submitting it to the Ugi reaction. In addition it

### The Journal of Organic Chemistry

should be noted that incubation of aldehyde *ent-9* in the same solvent with a tertiary amine (triethylamine) for 48 h led to only partial epimerization. Therefore we think that this complete epimerization is due to imine-enamine equilibrium and not to simple base mediated deprotonation of the aldehyde.<sup>25</sup> This result is in agreement with the pioneering work by Kelly,<sup>26</sup> who noticed partial epimerization of  $\alpha$ -chiral aldehydes during Ugi reactions. In our case complete conversion into *trans* isomers indicates that they should be much more stable.

Anyway, adducts **10a,b** could be useful intermediates for preparing heterocycles through  $S_N 2$  cyclizations.<sup>27</sup> By removing the *p*-methoxybenzyl group and the acetate we obtained chromatographically separable alcohols **11a,b**. Then, substitution of the OH group by one of the two secondary amides to give either a six-membered or a five-membered ring was attempted both on the diastereomeric mixture or on the isolated isomers. Initial experiments, involving formation of a mesylate followed by base treatment, were unsuccessful. We eventually found that 1,1'-sulfonyl diimidazole in combination with NaH<sup>28-30</sup> was able to promote the desired cyclization. Interestingly, only pyrrolidines were formed in good yields and no loss of stereochemical integrity was observed (each isomer afforded a single product). Separation of the diastereomers was easier at this level and therefore, under a synthetic point of view, it was more convenient to carry out the whole synthesis on the mixture. Even though the *trans* bicyclic derivatives **12a,b** are quite strained and therefore less thermodinamically stable than the corresponding *cis* ones (**12c,d**, Scheme 3), we did not observe any epimerization: this is due to the lack of an electron withdrawing group bound to the stereogenic center, which makes the deprotonation, responsible for the epimerization, unlikely.

In conclusion this synthetic protocol was able to afford the final adducts **12a,b** in good overall yields and is complementary to the synthesis of pyrrolidines through the Ugi-Joullié reaction of bicyclic imines, which affords *cis*-fused products instead.<sup>11,13</sup> Since monoacetate **8** is available as well, all four *trans*-fused pyrrolidines can be prepared.

In order to gain access to the *cis*-fused series as well, we turned our attention to the Passerini reaction.<sup>23,24</sup> which was expected to be less troublesome in terms of epimerization.<sup>31</sup>

In this case we chose to start from azidoaldehyde **14** instead of acetoxyaldehyde **9**. Passerini reactions of aldehyde **9** would afford doubly acylated diols, where the two ester moieties were expected to be difficult to differentiate, on the basis of preliminary experiments carried out by us on similar adducts. An alternative strategy would involve the hydrolysis of both esters to give a diol, followed by double substitution of the corresponding dimesylate by ammonia or a synthetic equivalent of it, to give a pyrrolidine. However, in our hands this approach was found to be inefficient, due to the easy formation of a tetrahydrofuran. Therefore, we decided to differentiate the two arms before the Passerini step, converting monoacetate **8** into azidoaldehyde **14** (Scheme 3) through a straightforward procedure, already applied by us in similar cases.<sup>11</sup>

Pleasingly, azidoaldehyde 14 underwent a model Passerini reaction with *n*-butyl isocyanide and propionic acid in high yield and, most importantly, with no epimerization at all. The whole sequence from monoacetate 8 to compounds 15a,b can be carried out without any intermediate purification and with an excellent overall yield (88%). Unfortunately, adducts 15 were obtained as a nearly 1:1 separable diastereomeric mixture. In order to obtain pyrrolidines 12 from these adducts, we carried out a two-step protocol involving: a) azide reduction with concomitant acyl migration; b)  $S_N2$  cyclization of the resulting secondary amide onto the secondary alcohol. Starting from 15a, both steps worked out in excellent yields to give pyrrolidine 12c as a single isomer.

The first stage resembles the PADAM (Passerini – amine deprotection – acyl migration) protocol, where the acyl group introduced onto the aldehyde oxygen during the Passerini reaction, undergoes a subsequent *O* to *N* acyl migration to give peptidomimetic structure. This protocol was first introduced by us starting from  $\alpha$ -aminoaldehydes,<sup>32</sup> and was recently extended to  $\beta$ -aminoaldehydes.<sup>33</sup> Now aldehyde **14** is equivalent to a  $\gamma$ -aminoaldehyde and therefore the results reported here further extend the scope of the strategy. As far as the cyclization step is concerned, in this instance 1,1'-sulfonyl diimidazole worked poorly and the best cyclization yields were obtained by mesylation of the alcohol followed by base-mediated cyclization. Under these conditions the yield of **12c** from **16a** was 91%.

However, when we repeated the cyclization on epimer **16b**, we surprisingly obtained a 2.7:1 mixture of **12c** (major) and **12d** (minor). Clearly, while **16a** reacts in a stereospecific manner (most likely with complete inversion of configuration), **16b** gives a non stereospecific transformation. The

reaction of **16b** is also slower and some unreacted mesylate of **16b** is recovered. Therefore a possible explanation is that, being cyclization of the mesylate of **16b** sluggish, there is enough time for it to equilibrate to **16a**, which, by contrast, reacts faster. The equilibration may take place through base-mediated enolization. Thus a mixture of **16a** and **16b** could be cyclized to give mostly **12c**, which was isolated in pure diastereomeric form in 73% yield! Also a small amount (10%) of **12d** was obtained. This means that **12c** can be produced in a stereoconvergent way with an overall yield of 55% from monoacetate **8**.

The relative and absolute configuration of adduct **12c**, obtained through the Passerini route described in Scheme 3, was unambiguously established by comparison with the major product obtained through Ugi-Joullié reaction of cyclic imine **6a**, prepared as previously described,<sup>34</sup> with propionic acid and *n*-butyl isocyanide. This reaction afforded, as major product, compound **12c**, that was identical (NMR, TLC,  $[\alpha]_D$ ) with the one obtained from **16a**. The Ugi-Joullié reaction also gave a small amount of all-*cis* compound **12d** (d.r. = 92:8). This was identical (NMR, TLC) with the minor adduct obtained from **16b** (as above described, **16b** afforded a mixture of **12c** and **12d**). The Ugi-Joullié reactions on **6a** were already demonstrated to afford preferentially, with high d.r., the *trans* adducts.<sup>13</sup> Since isomers **12a** and **12b**, obtained through the Ugi route described in Scheme 2, were clearly different from **12c** and **12d** (NMR, TLC), although having spectroscopic and MS data consistent with the same constitutional formula, the 3a-6a relative configuration must necessarily be *trans*.

The 1-6a relative configuration of **12a** and **12b** was established by the values of  $J_{1-6a}$  at <sup>1</sup>H NMR. This value is larger (9.9 Hz) for all-*trans* isomer **12a** than for 1-6a *cis* epimer **12b** (7.8 Hz.). Moreover, in **12b** there is a large nOe between *H*-1 and *H*-6a, which is not possible in **12a**. To further corroborate these assumptions, we carried out a minimization using ChemBio3D Ultra (CambridgeSoft)(PM3). These bicyclic systems were found to be quite rigid: apart from conformations deriving from rotation of the single bonds outside the ring, only one significant conformation of the bicyclic system was

### The Journal of Organic Chemistry

found. The calculated dihedral angles (*H*-1 - *H*-6a) for the four isomers are:  $-159.3 \circ (12a)$ ,  $-36.2 \circ (12b)$ , 122.7 ° (12c), 12.7 ° (12d), which are consistent with the experimental J values.

In conclusion the complementarity of Ugi and Passerini reactions, and the availability of both **8** and *ent*-**8** allowed us to prepare in good yields 6 out of 8 possible stereoisomers of pyrrolidines **12**, the remaining two, namely **12d** and *ent*-**12d**, being accessible only in low yield. The number of steps from desymmetrized monoacetates **8** or *ent*-**8**, is comparable, for both routes, to an alternative approach to pyrrolidines, previously demonstrated by us on similar substrates, where monoacetates are first converted into pyrrolines, followed by the Ugi-Joullié multicomponent reaction.<sup>11</sup> Moreover the here described approaches are stereochemically more versatile, since 6 stereoisomers (instead of 2) may be obtained. Finally, the procedure herein avoids the intermediacy of pyrrolines, which are sometimes not easily manipulated due to their tendency to polymerize.

As a first application of this methodology, we decided to develop a new efficient synthesis of an important API, Telaprevir **17** (Scheme 4). This compound is one of the most innovative drugs launched during the last ten years.<sup>35,36</sup> It is indeed one of the two first specific drugs directed against Hepatitis C, a severe and widely distributed disease. Approximately 170 million people worldwide are chronic carriers of this virus (2% of the world's population). The biological target of Telaprevir is a specific viral serine protease, and it is effective for genotype 1 of the virus. Although the treatment of HCV with antiviral drugs is still quite expensive, it is anticipated that the advent of generic drugs will strongly lower the cost, making this drug available to a larger population, especially in less-developed countries. For this purpose, cost-effective syntheses of this active principle are needed, and multicomponent reactions can be a good way to achieve this goal, as already demonstrated by Ruijter and others.<sup>5</sup>

SCHEME 4. Initially planned retrosynthesis of Telaprevir 17

The planned retrosynthesis is shown in Scheme 4. Telaprevir can be obtained through a Passerini reaction on aldehyde 18, which derives from protected alcohol 19. We wanted to prepare intermediate 19 in a very convergent way, employing the same strategy above described for the simple model 12c, which has the same absolute and relative configuration of our target. 19 Could be in principle obtained in just two linear steps after the Passerini reaction of peptide  $20^5$  with azidoaldehyde 14 and a suitably protected isocyanide 21 derived from L- $\alpha$ -aminopentanoic acid. In order to check the feasibility of this approach, we initially used *n*-butyl isocyanide as a simplified model for 21.

However, the reaction of peptide **20** with aldehyde **14** and *n*-butyl isocyanide failed to give the expected Passerini product. Under the typical Passerini conditions, **20** was nearly completely converted into the corresponding oxazolone **22** (Scheme 5).

We think that  $\alpha$ -addition to the isocyanide takes place normally, to give the usual intermediate. However, at this level, the activated acyl group is attached by the oxygen of the amide bond between cyclohexylglycine and *tert*-leucine. This reaction is evidently faster than the usual acyl migration onto the free hydroxy group. Formation of this type of oxazolones is a well known problem encountered during coupling of peptide acids.<sup>37</sup> However, these compounds are not isolated, since they can still react with amines to give amides, their intermediate formation being deemed responsible of racemization/epimerization of the obtained coupling product. In this case, the absence of a good nucleophile like an amine makes this adduct stable enough to be isolated.

It is interesting to note that the behavior of acid **20** is specific for the Passerini reaction, since it can be used as input in Ugi-Joullié reactions without any problems, as reported by Ruijter et al.,<sup>5</sup> and confirmed by us as well.

Thus we had to redesign our synthesis, employing as the carboxylic component, Boc protected L*tert*-leucine, with the intention to add later the other fragments (Scheme 6). The Passerini reaction of **22**  with aldehyde 14 (prepared once again by Swern oxidation of alcohol 13) proceeded in good (unoptimized) yield to give 23a,b (a:b 42:58). However, the next Staudinger-acyl migration protocol turned out to be troublesome. Probably because of the steric bulk of the acyl residue, migration was sluggish, required the addition of a base and the yield was unacceptably low.

Thus, we decided to shift to the route depicted on the left (Scheme 6), which involves the same number of steps and is based on a "truncated" Passerini reaction followed by azide reduction and acylation. Among the various reported methods for performing "truncated" Passerini,<sup>31</sup> the best results were obtained using boric acid.<sup>38,39</sup> The resulting alcohols **24a,b** were then straightforwardly converted into **25a,b** in good yield, proving that this second pathway was definitely more efficient. This time the **a:b** diastereomeric ratio was 59:41, therefore slightly favoring the correct isomer for Telaprevir synthesis. Anyway, the final cyclization was carried out on the diastereomeric mixture, being confident in the stereoconvergent conversion into **26**. Actually this isomer was isolated in good yield, whereas only traces of the epimer could be detected. Finally, the complete peptide chain was smoothly installed to afford **27**. We found out that a stepwise introduction of the remaining two fragments was more efficient, because of partial epimerization observed when the pre-assembled dipeptide was directly used.

Having proved on model compounds that the key intermediate could be accessed by the truncated Passerini protocol, we moved on to apply it to the synthesis of Telaprevir. Towards this goal we needed chiral, enantiomerically pure, protected isocyanides **33** or **34**, that were prepared starting from commercially available L- $\alpha$ -aminopentanol **28** (Scheme 7).

### SCHEME 7. Synthesis of α-aminopentanol derived isocyanides

In the case of **33** we introduced first the formyl group and then the benzoyl protection, whereas for **34** it was better to introduce first the benzyl ether and then to formylate the amine. In both cases dehydration gave in high yields the required isocyanides.

We first employed isocyanide **33** (Scheme 8). The synthesis proceeded even better than for the model compound. Actually, not only the truncated Passerini gave a nearly quantitative yield (after solvent optimization) but it turned out to be more diastereoselective, giving a 2:1 mixture of **35a** and **35b**. After introduction of protected L-*tert*-leucine, cyclization was also in this case stereoconvergent. However, while the cyclization of the mesylate of pure **36a** gave good results under the usual conditions (NaH, DMF), in the case of **36a,b** we needed to optimize the reaction, finding that the best conditions involved lithium hexamethyldisilazide (LiHMDS) in THF. Under these conditions, only isomer **37** was isolated in 63% yield along with 12% of the unreacted mesylate derived from **36b**. Attempts to obtain a complete conversion increasing the reaction times or the amount of base failed, due to fragility of the benzoate under basic conditions. The pyrrolidine **37** was finally converted into alcohol **39** by sequential acylations and deprotection.

The incomplete conversion into the cyclization product prompted us to explore an alternative route to **39**, using the more robust benzyl protection, and hence isocyanide **34** (Scheme 9). Moreover, we thought that the synthesis of azidoaldehyde 14 through Swern oxidation at -78 °C could have not been ideal for large scale production.

Recently, various methods for the one-pot conversion of alcohols into Passerini adducts by in situ oxidation have been reported. The reagents used are o-iodoxybenzoic acid (IBX),<sup>40-42</sup> Dess-Martin periodinane,<sup>5</sup> or dioxygen in presence of suitable catalysts.<sup>43</sup> However none of these conditions seemed suitable in our case: IBX is poorly soluble and reported to be shock sensitive,<sup>44</sup> Dess-Martin

### SCHEME 9. Synthesis of key intermediate 40 through the "benzyl" route

Page 17 of 62

### The Journal of Organic Chemistry

periodinane is quite expensive and its reactions are typically slow, and the catalytic oxidation with dioxygen requires an excess of isocyanide. Therefore we searched for a stoichiometric oxidant that would be commercially available, safe, affordable, and compatible with a subsequent one-pot Passerini reaction. We eventually found out that iodosobenzene diacetate (DIB) in the presence of catalytic TEMPO radical ((2,2,6,6-tetramethyl-1-piperidinyloxy)<sup>45</sup> was ideal for our purposes. This reagent is commercially available, not expensive and safe.<sup>46</sup> The oxidation reaction of **13** is fast enough (2.5 h) and it works very well in the same solvent that is appropriate for the Passerini reaction (CH<sub>2</sub>Cl<sub>2</sub>), allowing an easy one-pot procedure. The presence of acetic acid as an oxidation by-product does not allow to perform a truncated Passerini, but the acetyl group can be easily removed, without any intermediate work-up, after the MCR. In this way, crude alcohols **40a,b** were obtained in quantitative yield from alcohol **13**.

The crude mixture was pure enough to be used directly for the ensuing step to give **41a,b**. Finally, cyclization afforded pure diastereomer **42** in 65% yield (58% overall yield from azidoalcohol **13**!). It is worth noting that the cyclization yield was higher compared to the "benzoate" route, despite the lower diastereoselectivity of the Passerini reaction. Equilibration of the two mesylates, leading stereoconvergently to **42** was more efficient in this case, thanks to the higher stability of the benzyl protecting group under basic conditions. Pyrrolidine **42** was finally converted into alcohol **39**. This time we preferred to remove the benzyl protection before installing the piperazine fragment. The overall yield of **39** from azido alcohol **13** was 41%, compared to 34% with the "benzoate" route. Both pathways are efficient, but the "benzyl" route is in our opinion better also because of the higher operational simplicity.

To complete the synthesis of Telaprevir, alcohol **39** had to be oxidized and subjected to a Passerini reaction with cyclopropyl isocyanide. We first chose to use the "one-pot" oxidation-Passerini using DIB and catalytic TEMPO.<sup>47</sup> However, the relative volatility of cyclopropyl isocyanide and its

unpleasant smell makes its purification troublesome. This prompted us to explore the possibility to prepare *in situ* the isocyanide as well. In the literature we could find very few examples of this strategy,<sup>48,49</sup> but none of them seemed suited for our purposes. After various attempts, we found out that the method of choice employed in situ prepared Burgess reagent.<sup>50</sup> The crude isocyanide solution obtained in this way can be directly used without the need of troublesome purification operations. We believe that the here reported method for the generation of a crude isocyanide to be directly used without any purification may find widely application in IMCRs. In this way we were able to obtain Passerini adduct 44 (Scheme 10) through in situ generation of both the aldehyde (from the alcohol) and the isocyanide (from the formamide). However, the yield turned out to be only moderate. Therefore we searched for other oxidation methods, again avoiding those requiring expensive or unsafe reagents. We eventually found that an excellent overall yield (84%) of the two steps (oxidation-Passerini) could be achieved by using the Parikh–Doering method,<sup>51</sup> although in this case a brief extractive work-up of the intermediate aldehyde had to be performed prior to treatment with the *in situ* generated isocvanide. The two-step conversion of Passerini adduct 44 into Telaprevir was finally carried out as previously described<sup>5</sup>

In conclusion we were able to set up a convenient synthesis of Telaprevir, also amenable for upscaling, from desymmetrized monoacetate **8**. The overall yield from this biocatalytically derived chiral building block is a remarkable 26.4%. From the stereochemical point of view, all three stereogenic centers are fully controlled thanks to the enantioselective enzymatic desymmetrization and to the stereoconvergent cyclization step that overcomes the low diastereoselectivity of the Passerini reaction. Although the synthetic pathway is longer and less convergent than the one reported by Ruijter and others,<sup>5</sup> all steps are operationally simple and employ inexpensive reagents. Furthermore, the biocatalytic step makes use of a cheap and commercially available lipase, avoiding the preparation and maintenance of a specific bacterial culture to produce the needed proprietary MAO-N enzyme (MonoAmine Oxidase). Finally, this synthetic approach allowed us to deeply explore the behaviour of chiral aldehydes derived from enzymatic desymmetrization of *meso* diols in Passerini and Ugi reactions and our findings (including the capability to obtain all possible stereoisomers of a given pyrrolidine)

can be precious for the preparations of other heterocycles and other biologically active peptidomimetics. Scheme 11 reviews the four alternative strategies based on IMCRs to access chiral pyrrolidines. They are: the desymmetrization of *meso* pyrrolidines followed by Ugi-Joullié reaction;<sup>13</sup> the desymmetrization of *meso* diols followed by conversion into both enantiomers of pyrrolines and again by Ugi-Joullié reaction;<sup>11</sup> the Ugi and Passerini approaches described in this paper. Studies directed to the application of IMCRs to aldehydes derived from other desymmetrized *meso* diols are in progress.

# SCHEME 11. Comparison of the various strategies for the stereocontrolled synthesis of bicyclic pyrrolidines

### **Experimental Section**

### **General Experimental Methods.**

NMR spectra were taken at r.t. in CDCl<sub>3</sub> or in d<sub>6</sub>-DMSO at 300 MHz (<sup>1</sup>H), and 75 MHz (<sup>13</sup>C), using, as internal standard, TMS (<sup>1</sup>H NMR in CDCl<sub>3</sub>; 0.000 ppm) or the central peak of DMSO (<sup>1</sup>H NMR in d<sub>6</sub>-DMSO; 2.506 ppm) or the central peak of CDCl<sub>3</sub> (<sup>13</sup>C in CDCl<sub>3</sub>; 77.02 ppm), or the central peak of

DMSO (<sup>13</sup>C in d<sub>6</sub>-DMSO; 39.43 ppm). Chemical shifts are reported in ppm ( $\delta$  scale). Peak assignments were made with the aid of gCOSY and gHSQC experiments. In ABX system, the proton A is considered upfield and B downfield. NMR spectra of *N*-acylpyrrolidines and of Ugi adducts have always been recorded at various temperatures. At temperatures  $\leq 40$  °C, two sets of signals are often detected, because of the presence of a mixture of rotamers at the tertiary amide (M = major, m = minor). At high temperature (120 °C) coalescence is observed, demonstrating that the two sets of signals are due to conformers (and not to diastereomers or different products). However, since at 120°C several signals become broad, we preferred to report and describe here the spectra recorded at low temperatures.<sup>52</sup>

IR spectra were recorded as solid, oil, or foamy samples, with the ATR (attenuated total reflectance) technique or as CHCl<sub>3</sub> solutions. TLC analyses were carried out on silica gel plates and viewed at UV  $(\lambda = 254 \text{ nm or } 360 \text{ nm})$  and developed with Hanessian stain (dipping into a solution of  $(NH_4)_4MoO_4 \cdot 4H_2O$  (21 g) and  $Ce(SO_4)_2 \cdot 4H_2O$  (1 g) in  $H_2SO_4$  (31 mL) and  $H_2O$  (469 mL) and warming). R<sub>f</sub> values were measured after an elution of 7–9 cm. HRMS was performed by employing electron impact ionization; the analyzer is trisector magnetic Sector а (electrostatic/magnetic/electrostatic EBE mass spectrometer). GC-MS analyses were performed on column HP-1, 0.33 µm, 0.201 mm i.d., 12 m. Analysis conditions are as follows: solvent delay 2 min, mass range 33-600, injector temperature 250 °C, detector temperature 280 °C, MS temperature around 170 °C, starting temperature 50 or 70 °C, starting time 2 min, temperature gradient 20 °C/min, final temperature 260 °C, flux through column 1.0 mL/min, split ratio 100:1, sample concentration 1 mg/mL, amount injected 1 µL. Column chromatography was done with the "flash" methodology by using 220–400 mesh silica. Petroleum ether (40–60  $^{\circ}$ C) is abbreviated as PE. All reactions employing dry solvents were carried out under nitrogen.

(1S,2R)-2-(Hydroxymethyl)cyclopentyl)methyl acetate 8. Supportation of Amano PS Lipase. It was supported on Celite<sup>®</sup> following the same procedure already described by us for Pig Pancreatic Lipase (SPPL-4).<sup>22</sup> (1 g of this supported enzyme corresponds to 0.23 g of original Lipase). To a solution of meso-diol 7 (5.00 g, 38.4 mmol, 87% purity by GC) (obtained by LiAlH<sub>4</sub> reduction of ciscyclopentane-1,2-dicarboxylic anhydride)<sup>16-18</sup> in vinyl acetate (190 mL) cooled to 0 °C, freshly activated powered 3 Å molecular sieves (0.50 g) and supported Amano PS (3.25 g) were added. The reaction mixture was stirred at 0 °C for 17 h, then filtered through a sintered funnel and washed with CH<sub>2</sub>Cl<sub>2</sub> (100 mL). The filtrate was concentrated and the residue was eluted from a column of silica gel with PE-Et<sub>2</sub>O (from 2:1 to 1:3) to give 8 (6.39 g, 97%, e.e. = 97%) as an oil.  $R_f = 0.56$  (PE-Et<sub>2</sub>O 1:2).  $[\alpha]_{D}$  +7.30 (c=2.13, CHCl<sub>3</sub>). Lit. for (1*R*.2*S*) enantiomer: -8.2.<sup>21</sup> <sup>1</sup>H NMR (CDCl<sub>3</sub>, 25 °C):  $\delta$  = 4.03 and 4.12 (AB part of an ABX system,  $J_{AB} = 11.0$ ,  $J_{AX} = 6.9$ ,  $J_{BX} = 7.4$  Hz, 2 H,  $CH_2OAc$ ), 3.56 and 3.66 (AB part of an ABX system,  $J_{AB} = 10.9$ ,  $J_{AX} = 6.8$ ,  $J_{BX} = 7.5$  Hz, 2 H,  $CH_2OH$ ), 2.35 (hexuplet, 1 H, J =7.2 Hz, CH), 2.23 (hexuplet, 1 H, J = 7.4 Hz, CH), 2.07 (s, 3 H, CH<sub>3</sub>), 1.98 (br s, 1H, OH), 1.36-1.87 (m, 6 H, 3 CH<sub>2</sub>). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 25 °C):  $\delta$  = 171.2 (CO), 65.2 (CH<sub>2</sub>), 63.2 (CH<sub>2</sub>), 44.0 (CH), 39.7 (CH), 28.8 (CH<sub>2</sub>), 27.9 (CH<sub>2</sub>), 23.0 (CH<sub>2</sub>), 21.0 (CH<sub>3</sub>). (*1R,2S*)-2-(Hydroxymethyl)cyclopentyl)methyl acetate *ent*-8. A solution of *meso*-diol 7 (1.99 g, 15.4 mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (30 mL) at room temperature was treated with triethylamine (8.5 mL, 61.5 mmol), 4-dimethylaminopyridine (0.38 g, 3.1 mmol) and acetic anhydride (3.6 mL, 38.4 mmol). The

mixture was stirred at room temperature for 1 h, then it was treated with saturated aq NaHCO<sub>3</sub> solution (80 mL) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (100 + 50 +50 mL). The combined organic phases were washed with brine (50 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated. The residue was eluted from a column of silica gel with PE-Et<sub>2</sub>O (from 3:1 to 2:1) to give the diacetate<sup>19-21</sup> (3.20 g, 97%) as an oil. A suspension of this diacetate (2.61 g, 12.18 mmol) in THF (8.7 ml) was treated with 1 M pH 7 phosphate buffer (K<sub>2</sub>HPO<sub>4</sub>/KH<sub>2</sub>PO<sub>4</sub>) (87 ml), at 20 °C, and then with Amano PS lipase (550 mg). The suspension was stirred at 20 °C for 21 h. The mixture was saturated with NaCl, diluted with AcOEt and filtered through a celite cake, washing thoroughly with AcOEt. The phases were separated and the organic phase dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated. The residue was eluted from a column of silica gel with PE-Et<sub>2</sub>O (1:1 to 1:2) to give *ent-*8 (1.68 g, 80%, e.e. 95%) as an oil. [ $\alpha$ ]<sub>D</sub> –7.20 (c=2.27, CHCl<sub>3</sub>). Lit.: –8.2.<sup>21</sup> The other spectroscopic data were identical to those of enantiomer 8.

**Determination of e.e.s of 8 and** *ent-8*. A solution of monoacetate **8** (4.0 mg, 23.8 µmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (1 mL) was cooled to 0 °C and treated with DMAP (5.8 mg, 47.6 µmol) and (*R*)- $\alpha$ -methoxy- $\alpha$ -trifluoromethylphenylacetyl chloride (6.7 µL, 35.7 µmol). The mixture was allowed to reach room temperature for 50 min, then it was concentrated. The crude was purified by preparative TLC (PE-Et<sub>2</sub>O 2:1) to give the corresponding Mosher ester as an oil (7 mg, 0.025 mmol, 76%). <sup>1</sup>H-NMR analysis allowed determination of e.e.s through integration of CH<sub>2</sub>OCO signals.

(2*S*,1'*R*,2'*R*) and (2*R*,1'*R*,2'*R*) 2-(2-(Acetoxymethyl)cyclopentyl)-*N*-butyl-2-(*N*-(4methoxybenzyl)propionamido)acetamides 10a,b. To a solution of DMSO (0.62 mL, 8.70 mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (20 ml), at -70 °C under nitrogen atmosphere, a solution of oxalyl chloride in dry CH<sub>2</sub>Cl<sub>2</sub> (1.43 M, 4.5 mL) was added. The solution was stirred for approx. 10 min, until effervescence ceased. A solution of *ent*-**8** (0.60 g, 3.48 mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (10 + 4 ml) was added dropwise, and the solution

was stirred for 10 min at -70 °C. N,N-Diisopropylethylamine (2.80 mL, 16.35 mmol) was then added and the solution was stirred for 2 h at -70 °C and 1.5 h at -50 °C. After this time the reaction mixture was poured into a mixture of 5% aq. (NH<sub>4</sub>)H<sub>2</sub>PO<sub>4</sub> (70 mL) and 1 M HCl (5 mL) (final pH = 4) and extracted with  $CH_2Cl_2$  (100 + 30 ml). The organic layer was washed with saturated aq NaHCO<sub>3</sub> solution (20 mL), water (2 x 20 mL) and brine (20 mL), dried (Na<sub>2</sub>SO<sub>4</sub>) and concentrated. The resulting crude aldehyde ent-9 was at once taken up in trifluoroethanol (7 mL) and treated with freshly activated 4 Å powdered molecular sieves (87 mg), *p*-methoxybenzylamine (644 μL, 4.93 mmol), propionic acid (315 µL, 4.22 mmol) and *n*-butylisocyanide (441 µL, 4.22 mmol). The reaction mixture was stirred at room temperature for 48 h, then the molecular sieves were filtered away and the solvent evaporated. The residue was eluted from a column of silica gel with PE-AcOEt (4:1  $\rightarrow$  1:1) to give **10a,b** (1.14 g, 73%) as a 54:46 mixture of diastereoisomers (HPLC analysis; Synergi Hydro-RP 150x3 mm, 4µm, temp. 21 °C, flow = 0.4 mL/min, mobile phase H<sub>2</sub>O/CH<sub>3</sub>CN from 90:10 to 0:100 in 30 min.  $R_t$  (a) = 20.52 min, (b) = 21.08 min). Note that the relative configuration has not been assigned at this level. Therefore we do not know if **10a** is the precursor of **11a** or of **11b**.  $R_f = 0.18$  (PE-Et<sub>2</sub>O 1:2) (the two diastereomers were not separated); <sup>1</sup>H NMR (CDCl<sub>3</sub>, 25 °C):  $\delta = 7.04$  (*a*+*b*) (dd, J = 8.4 (o), 4.8 (m) Hz, 2 H, ArH), 6.82 (a+b) (dd, J = 8.4 (o), 2.7 (m) Hz, 2 H, ArH), 6.50 (a+b) (broad s, 1 H, NH), 4.68 and 4.53 (a+b) (AB syst., J = 17.1 Hz, 2 H, CH<sub>2</sub>-PMB), 4.61-4.46 (a+b) (m, 1 H, CH-N), 4.04 and 4.90 (a) (AB part of ABX syst.,  $J_{AB} = 12.9$ ,  $J_{AX} = 4.8$ ,  $J_{BX} = 7.2$  Hz, 1 H, CH<sub>2</sub>-OAc), 3.87 and 3.70 (b) (AB part of ABX syst.,  $J_{AB} = 10.8$ ,  $J_{AX} = 4.5$ ,  $J_{BX} = 8.4$  Hz, 1 H,  $CH_2$ -OAc), 3.79 (a) (s, 1.5 H, OMe), 3.78 (b) (s, 1.5 H, OMe), 3.23-2.97 (a+b) (m, 2 H, CH<sub>2</sub>NH), 2.57 (a+b) (center of m, 1 H, H-1), 2.47-2.19 (a+b) (m, 2 H, COCH<sub>2</sub>CH<sub>3</sub>), 2.06 (a) (s, 1.5 H, COCH<sub>3</sub>), 2.02 (b) (s, 1.5 H, COCH<sub>3</sub>), 1.91 (a+b) (centre of m, 1 H, H-2), 1.87-1.45 (a+b) (m, 6 H, H-3, H-4, H-5), 1.50-1.38 (a+b) (m, 2 H,  $CH_2CH_2NH$ ), 1.34-1.25 (*a*+*b*) (m, 2 H,  $CH_2CH_2CH_2NH$ ), 1.10 (*a*) (t, J = 7.5 Hz, 1.5 H,  $COCH_2CH_3$ ), 1.09 (b) (t, J = 7.5 Hz, 1.5 H, COCH<sub>2</sub>CH<sub>3</sub>), 0.91 (a+b) (t, J = 7.2 Hz, 3 H, CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>NH). <sup>13</sup>C

((1S,2R)-2-(Azidomethyl)cyclopentyl)methanol 13. A solution of monoacetate 8 (5.75 g, 33.4 mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (80 mL) was cooled to 0 °C and treated with Et<sub>3</sub>N (6.0 mL, 43.4 mmol) and methanesulfonyl chloride (3.1 mL, 40.1 mmol). The mixture was allowed to reach room temperature, kept 1 h at this temperature, then guenched with saturated ag  $NH_4Cl$  solution (60 mL) and extracted with  $CH_2Cl_2$  (50 + 100 mL). The combined organic phases were washed with water (60 mL), brine (60 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated to give the crude mesvlate (8.35 g) as an oil,  $R_f = 0.51$ (PE/CH<sub>2</sub>Cl<sub>2</sub>/Et<sub>2</sub>O 2:2:1). It was taken up in dry DMF (60 mL), treated with NaN<sub>3</sub> (5.42 g, 83.4 mmol), stirred for 17 h at 90 °C, then diluted with H<sub>2</sub>O (100 mL) and extracted with Et<sub>2</sub>O (200 + 100 mL). The combined organic phases were washed with brine (30 mL), dried ( $Na_2SO_4$ ), and concentrated. This crude azido acetate (6.42 g) was taken up in MeOH (60 mL) at room temperature, and added with a 1 M solution of KOH in MeOH (48.5 mL, 48.5 mmol). The reaction mixture was stirred at room temperature for 1 h, then treated with saturated ag NH<sub>4</sub>Cl solution (60 mL). After evaporation of most MeOH, the pH was adjusted to 5-6 by addition of 1 M HCl solution, and then the remaining aqueous phase was extracted with AcOEt (2 x 150 mL), washed with brine (40 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated to give crude azidoalcohol 13 (4.92 g, 95% from 8). This crude product could be used in the next step without further purification. An analytical sample was purified by flash chromatography eluting with 3:1 PE-Et<sub>2</sub>O to give **13** as an oil.  $R_f = 0.20$  (PE-Et<sub>2</sub>O 3:1).  $[\alpha]_D + 2.69$  (c=1.45, CHCl<sub>3</sub>). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 25 °C):  $\delta$  = 3.54-3.67 (m, 2 H, CH<sub>2</sub>OH), 3.29 and 3.45 (AB part of an ABX system, J<sub>4B</sub> = 12.3,  $J_{AX}$  = 6.9;  $J_{BX}$  = 7.8 Hz, 2 H,  $CH_2N_3$ ), 2.28 (hexuplet, J = 7.2 Hz, H-1 or H-2), 2.22 (center of m, 1 H, H-1 or H-2), 1.31-1.90 (m, 7 H). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 25 °C):  $\delta = 63.1$  (CH<sub>2</sub>), 52.6 (CH<sub>2</sub>), 44.0 (CH), 40.9 (CH), 29.7 (CH<sub>2</sub>), 27.8 (CH<sub>2</sub>), 23.1 (CH<sub>2</sub>). IR (CHCl<sub>3</sub>): v = 3673, 3613, 3497, 3040, 2947, 2871, 2391, 2097, 1601, 1446, 1216, 1011, 926, 658 cm<sup>-1</sup>. GC-MS (initial temp: 70 °C):  $R_t = 5.44$  min; m/z: 126 (M<sup>+</sup> – 29, 1.8 %), 96 (10), 95 (5.3), 86 (5.1), 82 (19), 81 (41), 80 (10), 79 (29), 77 (5.7), 70 (9.7), 69 (25), 68 (23), 67 (100), 66 (9.0), 65 (7.8), 59 (68), 57 (20), 56 (73), 55 (25), 54 (37), 53 (21),

46 (15), 43 (18), 42 (14), 41 (84), 40 (8.0), 39 (40). Elemental analysis: Found: C, 54.3; H, 8.5; N, 26.95%. C<sub>7</sub>H<sub>13</sub>N<sub>3</sub>O requires C, 54.17; H, 8.44; N, 27.08%.

2-(2-(Azidomethyl)cyclopentyl)-N-butyl-2-(2R, 1'S, 2'R)and (2S, 1'S, 2'R)(propionyloxy)acetamides 15a and 15b. To a solution of DMSO (0.57 mL, 8.05 mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (20 ml), at -78 °C under nitrogen atmosphere, a solution of oxalyl chloride in dry CH<sub>2</sub>Cl<sub>2</sub> (1.43 M, 4.70 mL) was added. The solution was stirred for approx. 10 min, until effervescence ceased. A solution of crude 13 (0.50 g, 3.22 mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (2 x 5 ml) was added dropwise, and the solution was stirred for 10 min at -78 °C. Triethylamine (2.10 mL, 15.13 mmol) was then added and the solution was stirred for 1 h at the same temperature. After this time the reaction mixture was poured into a mixture of 5% aq. (NH<sub>4</sub>)H<sub>2</sub>PO<sub>4</sub> (100 mL) and 1 M HCl (5 mL) (final pH = 4) and extracted with Et<sub>2</sub>O (2 x 100 ml). The organic layer was washed with saturated aq NaHCO<sub>3</sub> solution (80 mL), water (50 mL) and brine (50 mL), dried (Na<sub>2</sub>SO<sub>4</sub>) and co-evaporated with CH<sub>2</sub>Cl<sub>2</sub> to have a final solution of crude 14 in ca. 1 mL of CH<sub>2</sub>Cl<sub>2</sub>. It was diluted with other 6 mL of CH<sub>2</sub>Cl<sub>2</sub> and treated, at r.t., with propionic acid (286  $\mu$ L, 3.86 mmol) and *n*-butylisocyanide (401  $\mu$ L, 3.86 mmol). The reaction mixture was stirred at room temperature for 16 h, then concentrated. The residue was eluted from a column of silica gel with PE-Et<sub>2</sub>O (3:1  $\rightarrow$  1:1) to give **15a,b** (938 mg, 88% from **8**) as a 47:53 mixture by NMR analysis). For synthetic purposes, the mixture was used for the next steps. However, through careful chromatography with PE-Et<sub>2</sub>O, it was possible to obtain pure analytical samples of the two diastereomers.

**15a** (oil):  $R_f = 0.25$  (PE-Et<sub>2</sub>O 2:1).  $[\alpha]_D + 35.20$  (c=1.00, CHCl<sub>3</sub>). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 29 °C):  $\delta = 5.95$  (br t, J = 6.0 Hz, 1 H, NHBu), 5.20 (d, J = 6.3 Hz, 1 H, CHOCOEt), 3.45 and 3.19 (AB part of a ABX syst.,  $J_{AB} = 12.3$ ,  $J_{AX} = 6.9$ ,  $J_{BX} = 8.1$  Hz, 2 H, CH<sub>2</sub>N<sub>3</sub>), 3.26 (dt, J = 7.2, 6.0 Hz, 2 H, NH-CH<sub>2</sub>), 2.54 (quintuplet, J = 7.2 Hz, 1 H, H-1), 2.44 (q, J = 7.5 Hz, 2 H, CH<sub>2</sub>CO), 2.33 (sextuplet, J = 6.9 Hz, 1 H,

### (1S,3aR,6aS) N-Butyl-2-propionyloctahydrocyclopenta[c]pyrrole-1-carboxamides 12c.

*a) From pure* **16a**. A solution of **16a** (146 mg, 0.51 mmol) in dry  $CH_2Cl_2$  (5 mL) was cooled to  $-10 \degree C$  and treated with Et<sub>3</sub>N (98 µL, 0.71 mmol) and methanesulfonyl chloride (50 µL, 0.65 mmol). The

mixture was allowed to reach room temperature during 1 h, and then it was treated with saturated aq  $NH_4Cl$  solution (30 mL) and extracted with  $CH_2Cl_2$  (50 + 25 mL). The combined organic phases were washed with brine (20 mL), dried ( $Na_2SO_4$ ), and concentrated to give the crude mesylate (182 mg, quant. yield) as an amorphous solid. It was taken up in dry DMF (4 mL), cooled to 0 °C, and treated with sodium hydride (60% dispersion in mineral oil, 32 mg, 0.80 mmol). The mixture was stirred for 1 h at 0 °C, and then treated with saturated aq  $NH_4Cl$  solution (30 mL) and extracted with  $CH_2Cl_2$  (40 mL x 2). The combined organic phases were washed with brine (10 mL), dried ( $Na_2SO_4$ ), and concentrated. The crude product was eluted from a column of silica gel with AcOEt-MeOH (100:2) to give **12c** (125 mg, 91%) as an oil.

*b)* From the diastereomeric mixture of **16a** and **16b**. A 47:53 mixture of **15a,b** (938 mg, 3.02 mmol) was converted into **16a,b** (755 mg, 88%) as above described for the pure diastereomers. Then this mixture was treated exactly under the same conditions employed for conversion of pure **16a** into **12c** affording, after chromatography, **12c** (504 mg, 71%) plus **12d** (70 mg, 10%).

R<sub>f</sub> = 0.52 (AcOEt). [α]<sub>D</sub> –116.10 (c=1.6, CHCl<sub>3</sub>). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 29 °C) (84:16 mixture of rotamers *M* and *m*):  $\delta$  = 6.83 (*M*) (br t, *J* = 5.1 Hz, 1H, N*H*Bu), 5.97 (*m*) (br t, *J* = 5.1 Hz, 1 H, N*H*Bu), 4.41 (*M*) (d, *J* = 1.8 Hz, 1 H, *H*-1), 4.11 (*m*) (d, *J* = 1.8 Hz, 1 H, *H*-1), 3.66 (*M*) (dd, *J* = 10.8, 8.4 Hz, 1 H, *H*-3), 3.57 (*m*) (dd, *J* = 12.6, 6.0 Hz, *H*-3), 3.28-3.12 (*M*+*m*) (m, NH-CH<sub>2</sub>, 3 H, *H*-3), 3.01 (*M*) (tdd, *J* = 8.4 (d), 7.2 (d), 1.8 (t) Hz, 1 H, *H*-6a), 2.87 (*M*) (ddt, *J* = 12.3 (d), 8.1 (t), 4.5 (d) Hz, 1 H, *H*-3a), 2.78 (*m*) (center of m, 1 H, *H*-6a), 2.65 (*m*) (center of m, 1 H, *H*-3a), 2.32 (*M*+*m*) (app. octuplet, *J* = 7.5 Hz, 2 H, CH<sub>2</sub> of Et), 2.02-1.80 (*M*+*m*) (m, 2 H, 1 H of *H*-4, 1 H of *H*-6), 1.76-1.53 (*M*+*m*) (m, 2 H, *H*-5), 1.53-1.25 (*M*+*m*) (m, 6 H, 1 H of *H*-4, 1 H of *H*-6, 2 CH<sub>2</sub> of Bu), 1.14 (*M*) (t, *J* = 7.5 Hz, 3 H, COCH<sub>2</sub>CH<sub>3</sub>), 1.13 (*m*) (t, *J* = 7.5 Hz, 3 H, COCH<sub>2</sub>CH<sub>3</sub>), 0.93 (*m*) (t, *J* = 7.2 Hz, 3 H, CH<sub>3</sub> of Bu). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 29 °C) (84:16 mixture of rotamers *M* and *m*):  $\delta$  = 173.7 (*m*) (CO), 173.5 (*M*) (CO), 171.7 (*M*) (CO), 171.3 (*m*) (CO), 68.1 (*m*) (C-1), 66.1 (*M*) (C-1),

### (2R,1'S,2'R) and (2S,1'S,2'R) 2-(2-(((S)(2-((*tert*-butoxycarbonyl)amino)-3,3dimethylbutanoyl)amino)methyl)cyclopentyl)-*N*-butyl-2-hydroxyacetamides 25a and 25b.

*Method A.* To a stirred solution of **23a,b** (40 mg, 85  $\mu$ mol) in dry THF (1 mL) at 60 °C triphenylphosphine (25 mg, 95  $\mu$ mol) was added. After 1 h H<sub>2</sub>O (10  $\mu$ L) was added and stirring was continued for 4 h. After this time the solution was cooled to room temperature, and treated with Et<sub>3</sub>N (2.5  $\mu$ L, 18  $\mu$ mol). The reaction mixture was stirred at room temperature for 60 h, then concentrated. The crude product was eluted from a column of silica gel with 1:3 PE- AcOEt to give **25a,b** (11 mg, 29%) as an amorphous solid.

*Method B.* To a stirred solution of **24a,b** (100 mg, 0.39 mmol) in dry THF (3 mL) at 70 °C, triphenylphosphine (113 mg, 0.43 mmol) was added. After 2 h, H<sub>2</sub>O (0.14 mL) was added and stirring was continued for 3 h. After this time the solution was cooled to room temperature, and treated with *N*-methylmorpholine (NMM) (108  $\mu$ L, 0.98 mmol), L-Boc-*tert*-Leucine (99 mg, 0.43 mmol) and PyBOP (benzotriazol-1-yl-oxytripyrrolidinophosphonium hexafluorophosphate) (224 mg, 0.43 mmol). The reaction mixture was stirred at room temperature for 60 h, then treated with saturated aq NH<sub>4</sub>Cl solution (15 mL) and most THF was evaporated. The aqueous phase was extracted AcOEt (30 mL x 2), washed with saturated aq NaHCO<sub>3</sub> solution (30 mL) and brine (20 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated. The crude product was eluted from a column of silica gel with 1:1 PE- AcOEt with 1% MeOH to give **25a,b** (119 mg, 69%) as an amorphous solid. By repeated chromatography it was possible to obtain an analytical sample of pure **25a**, whose relative configuration was established through independent conversion into **26**.

**25a** (white foam):  $[\alpha]_D = +29.9$  (c=1.14, CHCl<sub>3</sub>). <sup>1</sup>H-NMR (CDCl<sub>3</sub>, 29 °C):  $\delta = 7.01$  (br s, 1 H, NHCH<sub>2</sub>CH), 6.92 (br t, J = 5.7 Hz, 1 H, NHBu), 5.50 (br d, J = 9.0 Hz, 1 H, NHBoc), 4.64 (d, J = 5.1 Hz, 1 H, OH), 4.20 (t, J = 4.2 Hz, 1 H, CHOH), 3.76 (d, J = 9.0 Hz, 1 H, CHNHBoc), 3.51 (quintuplet, J = 6.3 Hz, 1 H, 1H of NHCH<sub>2</sub>CH), 3.16-3.36 (m, 3 H, 1H of NHCH<sub>2</sub>CH, NHCH<sub>2</sub>-Pr), 2.33 (center of

### (*1S*,3*aR*,6*aS*) *N*-((*S*)-1-(Benzoyloxy)pent-2-yl)-2-((*S*)-2-((*tert*-butoxycarbonyl)amino)-3,3dimethylbutanoyl)octahydrocyclopenta[c]pyrrole-1-carboxamide 37.

Method A (from pure 36a). A solution of 36a (99 mg, 0.17 mmol) in dry  $CH_2Cl_2$  (2 mL) was cooled to 0 °C and treated with Et<sub>3</sub>N (62 µL, 0.44 mmol) and methanesulfonyl chloride (32 µL, 0.41 mmol). The mixture was allowed to reach room temperature during 1 h, then was quenched with a saturated aq NH<sub>4</sub>Cl solution (20 mL) and extracted with  $CH_2Cl_2$  (50 + 25 mL). The combined organic phases were washed with brine (20 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated to give the crude mesylate (120 mg, quant. yield) as an amorphous solid. It was taken up in dry DMF (1.8 mL) at 0 °C, and sodium hydride (60% dispersion in mineral oil, 15 mg, 0.38 mmol) was added. The mixture was stirred for 1 h at 0 °C, then treated with saturated aq NH<sub>4</sub>Cl solution (15 mL) and extracted with  $CH_2Cl_2$  (40 mL x 2). The combined organic phases were washed with brine (10 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated. The crude product was eluted from a column of silica gel with PE-AcOEt (4:1  $\rightarrow$  3:1) to give **37** (79 mg, 78%) as an amorphous solid.

*Method B (from 35a,b)*. A 66.3:33.7 mixture of **35a,b** (306 mg, 0.788 mmol) was converted into **36a,b** (67:33 ratio by NMR) (355 mg, 0.617 mmol, 78%) following the same procedure described for pure **36a**. It was taken up in dry CH<sub>2</sub>Cl<sub>2</sub> (7 mL), cooled to 0 °C and treated with Et<sub>3</sub>N (222  $\mu$ L, 1.65 mmol) and methanesulfonyl chloride (115  $\mu$ L, 0.147 mmol). The mixture was allowed to reach room temperature during 1 h, then was quenched with a saturated aq NH<sub>4</sub>Cl solution (40 mL) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (70 + 35 mL). The combined organic phases were washed with brine (20 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated to give the crude mesylates as a diastereomeric mixture (430 mg) as an amorphous solid. This mesylate was taken up in dry THF (8 mL) and treated with a freshly prepared

(from hexamethyldisilazane and 1.6 M *n*BuLi in hexanes) 0.4 M solution of lithium hexamethyldisilazide (LiHMDS) in THF-hexanes (1.54 mL, 0.617 mmol). The solution was stirred at 0 °C for 1 h and then treated with saturated aq NH<sub>4</sub>Cl solution (30 mL) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (50 mL x 2). The combined organic phases were washed with brine (20 mL), dried (Na<sub>2</sub>SO<sub>4</sub>), and concentrated. The crude product was eluted from a column of silica gel with PE-AcOEt (4:1  $\rightarrow$  3:1) to give **37** (216 mg, 63%) as an amorphous solid. The epimer of **37** was not detected, whereas we could isolate 13% of unreacted mesylate of **36b**.

 $R_f = 0.65$  (PE-AcOEt 2:1). [α]<sub>D</sub> –24.2 (c=1.06, CHCl<sub>3</sub>). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 29 °C): δ = 8.09-8.05 (m, 2H, aromatic H ortho to CO), 7.57 (tt, *J* = 7.5, 1.2 Hz, 1 H, aromatic H para to CO), 7.48-7.42 (m, 2 H, aromatic H meta to CO), 6.85 (br d, *J*= 8.1 Hz, 1 H, N*H*CH), 5.22 (br d, *J* = 9.9 Hz, 1 H, N*H*Boc), 4.42-4.26 (m, 5 H, *H*-1, C*H*NHBoc, NHC*H*, C*H*<sub>2</sub>OBz), 3.78-3.67 (m, 2 H, *H*-3), 2.95 (center of m, 1 H, *H*-6a), 2.80 (center of m, 1 H, *H*-3a), 1.89-1.75 (m, 2 H, 1 H of *H*-4 and 1 H of *H*-6), 1.72-1.33 (m, 8 H, 1 H of *H*-4, 1 H of *H*-6, *H*-5, 2 C*H*<sub>2</sub> of Pr), 1.42 (s, 9 H, Boc), 0.99 (s, 9 H, *t*Bu), 0.91 (t, 3 H, *J* = 7.2 Hz, C*H*<sub>3</sub> of Pr). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 29 °C): δ = 171.8, 170.9, 166.4 and 155.8 (4 CO), 133.1 (aromatic CH para to CO), 129.9 (*C*q), 129.7 (2 aromatic CH ortho to CO), 128.4 (2 aromatic CH meta to CO), 79.6 (Cq), 66.4 (CH-1), 66.2 (CH<sub>2</sub>OBz), 58.2 (CHNHBoc), 54.3 (CH<sub>2</sub>-3), 48.1 (CHNH), 44.7 (CH-6a), 43.1 (CH-3a), 35.3 (Cq), 33.9 (CH<sub>2</sub> of Pr). (*1S*,3*aR*,6*aS*) 2-((*S*)-2-((*S*)-2-Cyclohexyl-2-(pyrazine-2-carboxamido)acetamido)-3,3dimethylbutanoyl)-*N*-((*S*)-1-hydroxypent-2-yl)octahydrocyclopenta[c]pyrrole-1-carboxamide 39. *Method A*. To a solution of **38** (59 mg, 0.08 mmol) in MeOH (2 mL) at room temperature, potassium carbonate (14 mg, 0.10 mmol) was added. The reaction mixture was stirred at room temperature for 3 h, then treated with a saturated aq NH<sub>4</sub>Cl solution and extracted with AcOEt. The combined organic phases were washed with brine, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and concentrated. The crude product was purified by flash chromatography eluting with AcOEt-PE (5:1  $\rightarrow$  100:0) to give **39** (43 mg, 90%) as amorphous solid.

*Method B*. A solution of compound **43** (84 mg, 0.12 mmol) in MeOH/H<sub>2</sub>O/AcOH (4 mL:400  $\mu$ L:80  $\mu$ L) was treated with 10% Pd/C (24 mg) and hydrogenated at 1 atm and room temperature for 18 h. After filtration of the catalyst and evaporation of the solvent, the crude was taken up in CH<sub>2</sub>Cl<sub>2</sub> (2 mL), cooled (0 °C) and treated with CF<sub>3</sub>CO<sub>2</sub>H (1 mL). The solution was allowed to reach room temperature during 1 h, and then concentrated. The solution of the crude trifluroacetate salt in dry CH<sub>2</sub>Cl<sub>2</sub> (4 mL) was treated with *N*-methylmorpholine (NMM) (95  $\mu$ L, 0.86 mmol), pyrazinecarboxylic acid (17 mg, 0.13 mmol) and PyBOP (benzotriazol-1-yl-oxytripyrrolidinophosphonium hexafluorophosphate) (77 mg, 0.21 mmol). The reaction mixture was stirred at room temperature for 14 h, then treated with a saturated aq NH<sub>4</sub>Cl solution and extracted with AcOEt, washed with saturated aq NaHCO<sub>3</sub> solution and brine, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered and concentrated. The crude was purified by flash chromatography eluting with AcOEt-MeOH 99:1 to give the coupling product **39** (56 mg, 76% from **43**) as an amorphous solid.

 $[\alpha]_D$  –59.64 (c=1.00, MeOH). <sup>1</sup>H NMR (a mixture of conformers M/m in 8:1 ratio was observed. ## N-((S)-1-(Benzyloxy)pent-2-yl)-2-((S)-2-((tert-butoxycarbonyl)amino)-3,3-(1S.3aR.6aS)dimethylbutanoyl)octahydrocyclopenta[c]pyrrole-1-carboxamide 42. A solution of 41a,b (500 mg, 0.90 mmol) in dry CH<sub>2</sub>Cl<sub>2</sub> (10 mL) was cooled to 0 °C and treated with Et<sub>3</sub>N (440 µL, 3.20 mmol) and methanesulfonyl chloride (210 µL, 2.70 mmol). The mixture was allowed to reach room temperature in 1 h, then was quenched with a saturated ag NH<sub>4</sub>Cl solution (70 mL) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (70 + 50 mL). The combined organic phases were dried ( $Na_2SO_4$ ) and concentrated to give the crude mesylates (559 mg) as an amorphous solid. $R_f(\mathbf{a}) = 0.59$ , $R_f(\mathbf{b}) = 0.49$ (ETP/AcOEt 1:1). To a solution of these crude mesylates in dry DMF (10 mL) at 0 °C, sodium hydride (60% of a dispersion in mineral oil, 85 mg, 2.12 mmol.) was added. The mixture was stirred for 1 h at 0 °C, then treated with saturated aq NH<sub>4</sub>Cl solution (75 mL) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (80 mL x 2). The combined organic phases were dried ( $Na_2SO_4$ ), and concentrated. The crude product was eluted from a column of silica gel with PE-AcOEt (4:1 $\rightarrow$ 3:1) to give 42 (315 mg, 65%) as an amorphous solid and an unseparable mixture of its epimer and the mesylate of **41b** in 94:6 ratio (30 mg). $R_f = 0.48$ (PE-AcOEt 3:1). $[\alpha]_D - 85.20$ (c=1.00, CHCl<sub>3</sub>). <sup>1</sup>H-NMR (CDCl<sub>3</sub>, 29 °C): $\delta = 7.37-7.25$ (m, 5 H, aromatic H of Bn), 6.69 (br d, J = 8.7 Hz, 1 H, NHCH), 4.54-4.48 (AB syst., J = 12.0 Hz, 2 H, CH<sub>2</sub>Ph), 4.40 (d, J = 2.7 Hz, 1 H, H-1), 4.30 (br d, J = 10.2 Hz, 1 H, NHBoc), 4.03 (center of m, 1 H, NHCH), 3.77-3.66 (m, 2H, H-3), 3.46 and 3.44 (AB part of ABX syst., *J*<sub>AB</sub> = 9.6, *J*<sub>AX</sub> = 3.9, *J*<sub>BX</sub> = 4.2 Hz, 2 H, CH<sub>2</sub>OBn), 2.99 (tdd, *J* = 8.1, 6.0, 2.7 Hz, 1 H, H-6a), 2.81 (center of m, 1 H, H-3a), 1.95-1.80 (m, 2 H, 1 H of H-4 and 1 H of H-6), 1.75-1.25 (m, 8 H, 1 H of *H*-4, 1 H of *H*-6, *H*-5, 2 C $H_2$ of Pr), 1.42 (s, 9 H, Boc), 0.98 (s, 9 H, tBu), 0.87 (t, J = 7.2 Hz, 3 H, CH<sub>3</sub> of Pr). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 29 °C): $\delta$ = 171.7, 170.6 and 155.8 (3 CO), 138.2 (Cq), 128.3 (2 aromatic CH of Bn), 127.6 (3 aromatic CH of Bn), 79.6 (Cq), 73.1 (CH<sub>2</sub>Ph), 71.38 (CH<sub>2</sub>OBn), 66.4

HRMS (EI): m/z: [M]<sup>+</sup> Calcd for C<sub>39</sub>H<sub>62</sub>N<sub>4</sub>O<sub>6</sub> 682.4669; Found 682.4654.

# (*1S*,3*aR*,6*aS*) *N*-((*2SR*,3*S*)-2-acetoxy-1-(cyclopropylamino)-1-oxohexan-3-yl)-2-((*S*)-2-((*S*)-2-(cyclohexyl-2-(pyrazine-2-carboxamido)acetamido)-3,3-

dimethylbutanoyl)octahydrocyclopenta[c]pyrrole-1-carboxamides 44. In situ preparation of cyclopropyl isocyanide. To a solution of chlorosulfonyl isocyanate (21.93 g, 154.95 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (39 mL) a solution of MeOH (6.6 mL, 162.69 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (39 mL) was added at 0 °C in about 1 h. When the addition was complete, the reaction mixture was warmed to 20 °C and stirred for 30 minutes at the same temperature, then concentrated under vacuum to give the sulfamoyl chloride intermediate as a colorless solid which was taken up in toluene (305 mL) and warmed at 40 °C. This solution was added dropwise, in about 1 h, to a solution of Et<sub>3</sub>N (48.6 mL, 348.6 mmol) in toluene (105 mL) keeping the temperature between 25-30 °C. After complete addition the suspension was cooled at 0 °C and after 1 h filtered to give 53 g of the crude Burgess reagent containing 42% w/w of triethylamine hydrochloride by <sup>1</sup>H NMR. A solution of *N*-cyclopropylformamide (956 mg, 11.2 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (6 mL) was treated with the above described crude Burgess reagent (4.67 g,11.24 mmoL).

The reaction was monitored by GC and complete conversion was achieved in about 2 h. This  $CH_2Cl_2$  solution containing cyclopropyl isocyanide was used as such immediately in the following Passerini reaction.

Synthesis of 44. Alcohol 39 (4.48 g, 7.48 mmol) was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (25 mL) and DMSO (19 mL) and triethylamine (5.22 mL, 37.3 mmol) were added. The mixture was cooled to -10 °C and a solution of SO<sub>3</sub>·Pyridine complex (5.82 g, 36.6 mmol) in DMSO (18 mL) was added dropwise, keeping the temperature between -12 °C and -10 °C. After complete reaction (monitoring by HPLC) the reaction mixture was diluted with CH<sub>2</sub>Cl<sub>2</sub> and washed with water, then with 0.1 N HCl, then water again. The organic layer was dried (Na<sub>2</sub>SO<sub>4</sub>) and evaporated. The residue was taken up in CH<sub>2</sub>Cl<sub>2</sub> (7 mL) and added dropwise at 0 °C to the solution of crude cyclopropyl isocyanide (11.2 mmol) freshly prepared as described above. To the resulting reaction mixture AcOH (0.64 mL, 11.2 mmol) was then added at 0 °C. After 10 minutes the reaction mixture was warmed to room temperature and stirred at the same temperature for 18 h. The reaction was diluted with CH<sub>2</sub>Cl<sub>2</sub>, then quenched adding saturated aq NaHCO<sub>3</sub> solution. After phase separation the CH<sub>2</sub>Cl<sub>2</sub> solution was washed with a saturated aq NaHCO<sub>3</sub> solution, followed by water. The organic phase was dried (Na<sub>2</sub>SO<sub>4</sub>) and concentrated. The crude was purified by flash chromatography eluting with *n*-hexane-AcOEt (60:40  $\rightarrow$  0:100) to give 44 (4.55 g, 84%) as a colourless solid and as a diastereomeric mixture. The physical and spectral data were in agreement with those reported in the literature.<sup>5</sup>
